# 1 Nomenclature

$\vec{\alpha}_S$	Rotational structural acceleration, 3x1 vector
$\Delta t_{RD}$	Time step for the radiation memory effect calculations
$\zeta$	Wave elevation time history
$\pi$	Mathematical constant, pi
$\omega$	frequency (rad/s)
$\vec{\omega}_S$	Rotational structural velocities, 3x1 vector, currently not used
$\rho_f$	Density of the flooding/ballast fluid
$\rho_{MG}$	Density of marine growth
$\rho_W$	Water density
$\vec{a}_f$	Linear acceleration of the fluid, 3x1 vector
$\vec{a}_s$	Linear acceleration of the structure, 3x1 vector
$A$	Area of super member
$AM$	Added-mass, 6x6 matrix
$AM_F$	Added-mass due to flooding, 6x6 matrix
$AM_M$	Added-mass due to Morison's equations, 6x6 matrix
$AM_{MG}$	Added-mass due to marine growth, 6x6 matrix
$AM_{RP}$	Added-mass due to radiation problem applied to the WAMIT reference point, 6x6 matrix
$[B]$	Additional damping matrix, 6x6
$[B_{quad}]$	Additional quadratic drag matrix, 6x6
$[C]$	Member direction cosine 3x3 matrix, transforming local coordinates to global coordinates
$[C]$	Additional stiffness matrix, 6x6
$C_A$	Added-mass coefficient
$C_{A_{Ax}}$	Axial added-mass coefficient
$C_D$	Transverse viscous-drag coefficient
$C_{D_{Ax}}$	Axial viscous-drag coefficient
$C_P$	Transverse dynamic pressure coefficient
$C_{P_{Ax}}$	Axial dynamic pressure coefficient
$d$	Water depth, unsigned magnitude
$\vec{F}_0$	Additional preload, 3x1 vector
$\vec{F}_{AM}$	Total added mass forces from all contributing effects
$\vec{F}_{AM\_F}$	Added mass forces due to filled/ballasted fluid
$\vec{F}_{AM\_M}$	Added mass forces due to
$\vec{F}_{AM\_MG}$	Added mass forces due to marine growth

$\vec{F}_j$	Total forces and moments applied to node j, 6x1 vector
$\vec{F}_{ADD}$	Total loads due to preload, additional stiffness, and additional damping terms, 6x1 vector
$\vec{F}_B$	Buoyancy forces and moments applied to node, 6x1 vector
$\vec{F}_D$	Drag forces and moments applied to node, 6x1 vector
$\vec{F}_{F\_B}$	Buoyancy forces and moments due to flooding applied to node, 6x1 vector
$\vec{F}_{HS}$	Hydrostatic forces applied to the platform reference node, 6x1 vector
$\vec{F}_I$	Inertial forces and moments applied to node, 6x1 vector
$\vec{F}_{MG}$	Marine growth-related forces and moments applied to node, 6x1 vector
$\vec{F}_{RD}$	Radiation memory-effect force applied to platform reference point, 6x1 vector
$\vec{F}_W$	Incident-wave excitation force applied to platform reference point, 6x1 vector
$\vec{F}_{glb}^i$	Point buoyancy forces at the end cap of the ith member which connects to the super member
$\vec{F}_W$	Incident-wave excitation force applied to platform reference point, 6x1 vector
$\vec{F}_{WRP}$	Total loads at the WAMIT reference point from potential flow theory, 6x1 vector
$g$	Gravity, unsigned magnitude
$h_{ref}$	Reference depth for the near-surface current model
$i$	member or element index
$\hat{i}$	Unit vector along the local x-axis
$\hat{I}$	Unit vector along the global X-axis
$j$	node index, imaginary number constant
$\hat{j}$	Unit vector along the local y-axis
$\hat{J}$	Unit vector along the global Y-axis
$\hat{k}$	Unit vector along the local z-axis
$K$	Radiation kernel from potential flow theory, 6x6 matrix
$\hat{K}$	Unit vector along the global Z-axis
$kg$	Kilograms
$L_m$	Length of master cylinder of a super member
$L_{s_i}$	Length of the ith slave cylinder of a super member
$m$	Meters
$M$	Number of members connected to a given joint
$n$	the $n^{th}$ time step
$\hat{n}_i$	Outward facing normal for member the $i^{th}$ member. Parallel to the local $\hat{k}$ axis
$N$	Newtons
$p_{dyn}$	Fluid dynamic pressure
$R$	Outer radius of structural member
$R_m$	Outer radius of the super member's master cylinder
$R_{s_i}$	Outer radius of the ith slave cylinder which is part of a super member

$s$	seconds
$t$	time
$t_M$	Thickness of structural member
$t_{Me}$	Thickness of structural member at element end
$t_{MG_m}$	Marine-growth thickness on the master cylinder
$t_{MG_{s_i}}$	Marine-growth thickness on ith slave cylinder of a super member
$t_{Ms}$	Thickness of structural member at element start
$t_{MG}$	Marine-growth thickness
$U_{0NS}$	Reference current velocity for the near-surface current model
$U_{0SS}$	Reference current velocity for the sub-surface current model
$U_{NS}$	Current velocity at depth, Z, for the near-surface current model
$U_{SS}$	Current velocity at depth, Z, for the sub-surface current model
$\vec{v}_f$	Linear velocity of the fluid, 3x1 vector
$\vec{v}_{rel}$	Relative velocity, $\vec{v}_{rel} = \vec{v}_f - \vec{v}_s$ 3x1 vector
$\vec{v}_s$	Translational structural velocities, 3x1 vector
$V$	Volume of member (super member)
$V_i^c$	Volume of ith cylinder which is a part of the super member
$V_I$	Interior cavity volume of member (super member)
$V_{MG}$	added volume due to marine growth
$\begin{bmatrix} x & y & z \end{bmatrix}^T$	Position in the local, member coordinate system
$\begin{bmatrix} X & Y & Z \end{bmatrix}^T$	Position in the global, inertial coordinate system
$x_n^d$	Discrete states of the radiation solution
$XD_H$	Radiation damping history

## 2 Introduction

[HydroDyn](#) is a time-domain hydrodynamics module that has been coupled into the FAST wind turbine computer-aided engineering (CAE) tool to enable aero-hydro-servo-elastic simulation of offshore wind turbines. HydroDyn is applicable to both fixed-bottom and floating offshore substructures. This latest release of HydroDyn follows the requirements of the FAST modularization framework, couples to [FAST v8.08](#), and provides new capability (relative to prior versions) for modeling the hydrodynamic loading on multi-member substructures. HydroDyn can also be driven as a standalone code to compute hydrodynamic loading uncoupled from FAST.

HydroDyn allows for multiple approaches for calculating the hydrodynamic loads on a structure: a potential-flow theory solution, a strip-theory solution, or a combination of the two. Linear (Airy) wave theory with no wave stretching is used, and second-order theory is presently being added.

The potential-flow solution includes linear hydrostatic restoring, the added mass and damping contributions from wave radiation, including free-surface memory effects, and the incident-wave excitation from linear diffraction. The frequency-dependent hydrodynamic coefficients required for this solution must be supplied by a separate frequency-domain panel code (e.g., WAMIT) from a pre-computation step. The radiation memory effect can be calculated either through direct time-domain convolution or through a linear state-space approach, with a state-space model derived through the [SS Fitting](#) preprocessor.

The strip-theory solution may be preferable for substructures or members of substructures that are small in diameter relative to a typical wavelength. Strip-theory hydrodynamic loads can be applied across multiple interconnected members, each with possible incline and taper, and are derived directly from the undisturbed wave and current kinematics at the undisplaced position of the substructure. The strip-theory loads include the relative form of Morison's equation for the distributed fluid-inertia, added-mass, and viscous-drag components. Additional distributed load components include axial loads from tapered members and static buoyancy loads. Hydrodynamic loads are also applied as lumped loads on member endpoints (called joints). It is also possible to include flooding or ballasting of members, and the effects of marine growth. The hydrodynamic coefficients required for this solution come through user-specified dynamic-pressure, added-mass, and viscous-drag coefficients.

For some substructures and sea conditions, the hydrodynamic loads from a potential-flow theory must be augmented with the loads brought about by flow separation. For this, the viscous-drag component of the strip-theory solution may be included with the potential-flow theory solution. Another option available is to supply a global damping matrix (linear or quadratic) to the system to represent this effect.

When HydroDyn is coupled to FAST, HydroDyn receives the position, orientation, velocities, and accelerations of the (rigid or flexible) substructure at each coupling time step and then computes the hydrodynamic loads and returns them back to FAST. At this time, FAST's ElastoDyn structural-dynamics module assumes for a floating platform that the substructure (floating platform) is a six degree-of-freedom (DOF) rigid body. For fixed-bottom offshore wind

turbines, FAST's SubDyn module allows for structural flexibility of multi-member substructures and the coupling to HydroDyn includes hydro-elastic effects.

The primary HydroDyn input file defines the substructure geometry, hydrodynamic coefficients, incident wave kinematics and current, potential-flow solution options, flooding/ballasting and marine growth, and auxiliary parameters. The geometry of strip-theory members is defined by joint coordinates of the undisplaced substructure in the global reference system, with the origin at the intersection of the undeflected tower centerline with mean sea level (MSL). A member connects two joints; multiple members can use a common joint. The hydrodynamic loads are computed at nodes, which are the resultant of member refinement into multiple (*MDivSize* input) elements (nodes are located at the ends of each element), and they are calculated by the module. Member properties include outer diameter, thickness, and dynamic-pressure, added-mass and viscous-drag coefficients. Member properties are specified at the joints; if properties change from one joint to the other, they will be linearly interpolated for the inner nodes.

Section 3 details how to obtain the HydroDyn and FAST software archives and how to run both the stand-alone HydroDyn or HydroDyn coupled to FAST. Section 4 describes the HydroDyn input files. Section 5 discusses the output files generated by HydroDyn; these include echo files, wave-elevation outputs, a summary file, and the results file. Section 6 provides modeling guidance when using HydroDyn. The HydroDyn theory is covered in Section 7. Section 8 outlines future work, and Section 9 contains a list of references. Example input files are shown in Appendix A and B. A summary of available output channels are found in Appendix C. Instructions for compiling the stand-alone HydroDyn program are detailed in Appendix D. Appendix E tracks the major changes we have made to HydroDyn for each public release.

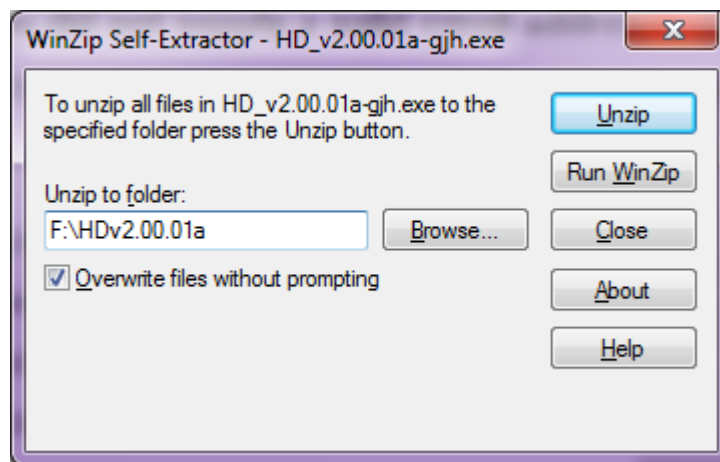

## 3 Running HydroDyn

### 3.1 Downloading the HydroDyn Software

#### 3.1.1 Stand-alone HydroDyn Archive

You can download the stand-alone HydroDyn archive from our web server at <http://wind.nrel.gov/designcodes/simulators/hydrodyn>. The file has a name similar to *HD\_v2.01.00.exe*, but may have a different version number. Run the downloaded self-extracting archive (.exe) to expand the archive into a folder you specify.

The archive contains the **bin**, **CertTest**, **Compiling**, **Documentation**, and **Source** folders. The **bin** folder includes the *HydroDynDriver\_win32.exe*, which is used to execute the stand-alone HydroDyn program. The **CertTest** folder contains a collection of sample HydroDyn input files. If you run the *CertTest.bat* DOS script, you can compare your results to the ones stored in the **NREL\_Results** subfolder. This manual may be found in the **Documentation** folder. The **Compiling** folder contains files for compiling the stand-alone *HydroDynDriver\_win32.exe* with either Visual Studio or gFortran. However, at this time, the software is not functional when compiled with gFortran. The Fortran source code is located in the **Source** folder.

#### 3.1.2 FAST Archive

You can download the FAST archive, which includes a coupling to HydroDyn, from our web server at <http://wind.nrel.gov/designcodes/simulators/fast8/>. The file has a name similar to *FAST\_v8.08.00.exe*, but may have a different version number. Run the downloaded self-extracting archive (.exe) to expand the archive into a folder you specify. The FAST executable is located in the archive's **bin** folder. Example models using the NREL 5-MW reference turbine and various substructures are located in the **CertTest** folder. These include Test19: OC3-Monopile, Test20: OC3-Tripod, Test21: OC4-jacket, Test22: ITI Energy barge, Test23: MIT/NREL tension-leg platform (TLP), Test24: OC3-Hywind spar buoy, and Test25: OC4-DeepCwind semi-submersible.

### 3.2 Running the Stand-alone HydroDyn

The stand-alone HydroDyn program, *HydroDynDriver\_win32.exe*, simulates hydrodynamic responses of your input model, without coupling to FAST. Unlike the coupled version, the stand-alone software requires the use of a driver file in addition to the primary HydroDyn input file. This driver file specifies initialization inputs normally provided to HydroDyn by FAST, as

well as the per-time-step inputs to HydroDyn. Both the HydroDyn summary file and the results output file are available when using the stand-alone HydroDyn, see Section 5 for more information regarding the HydroDyn output files.

Run the standalone HydroDyn software from a DOS command prompt by typing, e.g.

```
>HydroDynDriver_win32.exe MyDriverFile.dvr
```

where, *MyDriverFile.dvr* is the name of the HydroDyn driver file, as described in Section 4.2. The HydroDyn primary input file is described in Section 4.3.

### **3.3 Running HydroDyn Coupled to FAST**

Run the coupled FAST software from a DOS command prompt by typing, e.g.

```
>FAST_win32.exe Test22.fst
```

where, *Test22.fst* is the name of the primary FAST input file. This input file has a control flag to turn on or off the HydroDyn capabilities within FAST, and a corresponding reference to the HydroDyn input file. See the documentation supplied with FAST for further information.

## 4 Input Files

The user configures the hydrodynamic model parameters as well as the substructure geometry and properties via a primary HydroDyn input file. When used in stand-alone mode, an additional driver input file is required. This driver file specifies initialization inputs normally provided to HydroDyn by FAST, as well as the per-time-step inputs to HydroDyn.

No lines should be added or removed from the input files, except in tables where the number of rows is specified.

### 4.1 Units

HydroDyn uses the SI system (kg, m, s, N).

### 4.2 HydroDyn Driver Input File

The driver input file is only needed for the stand-alone version of HydroDyn and contains inputs normally generated by FAST, and are necessary to control the hydrodynamic simulation for uncoupled models. A sample HydroDyn driver input file is given in Appendix B.

Set the **Echo** flag in this file to TRUE if you wish to have *HydroDynDriver.exe* echo the contents of the driver input file (useful for debugging errors in the input file). The echo file has the naming convention of *OutRootName.dvr.ech*. **OutRootName** is specified in the HYDRODYN section of the driver input file. Set the gravity constant using the **Gravity** parameter. HydroDyn expects a magnitude, so in SI units this would be set to  $9.80665 \frac{m}{s^2}$ . **HDInputFile** is the filename of the primary HydroDyn input file. This name should be in quotations and can contain an absolute path or a relative path. All HydroDyn-generated output files will be prefixed with **OutRootName**. If this parameter includes a filepath, the output will be generated in that folder. **NSteps** specifies the number of simulation time steps, and **TimeInterval** specifies the time between steps.

Setting **WAMITInputsMod** = 0 forces all WAMIT reference point (WRP) input motions to zero for all time. If you set **WAMITInputsMod** = 1, then you must set the steady-state inputs in the WAMIT STEADY STATE INPUTS section of the file. Setting **WAMITInputsMod** = 2, requires the time-series input file whose name is specified via the **WAMITInputsFile** parameter. The WAMIT inputs file is a text-formatted file. This file has no header lines. Each data row corresponds to a given time step, and the whitespace separated columns of floating point values represent the necessary motion inputs as shown in Table 1. All motions are specified in the global inertial-frame coordinate system.

**Table 1. WAMIT Inputs Time-Series Data File Contents**

Column Number	Input	Units
1	Time step value	s
2-4	Translational displacements along X, Y, and Z	m
5-7	Rotational displacements about X, Y, and Z (small angle	radians

	assumptions apply)	
8-10	Translational velocities along X, Y, and Z	$\frac{m}{s}$
11-13	Rotational velocities about X, Y, and Z	$\frac{radians}{s}$
14-16	Translational accelerations along X, Y, and Z	$\frac{m}{s^2}$
17-19	Rotational accelerations about X, Y, and Z	$\frac{radians}{s^2}$

In a similar fashion, the input motions for the Morison members (strip-theory model) are set to zero if **MorisonInputsMod** = 0. If you select **MorsionInputsMod** = 1 then the motions at each substructure joint are set to the steady-state values given in the MORISON STEADY STATE INPUTS section. Currently, option 2 is unavailable for the Morison inputs.

The stand-alone HydroDyn does not check for physical consistency between motions specified for the WRP and Morison members in the driver file .

Setting **WaveElevSeriesFlag** to TRUE enables the outputting of a grid of wave elevations to a text-based file with the name *OutRootName.WaveElev.out*. The grid consists of **WaveElevNX** by **WaveElevNY** wave elevations (centered at  $X=0$ ,  $Y=0$ ) with a  $dX$  and  $dY$  spacing in the global inertial-frame coordinate system. These wave elevations are distinct and output separately from the wave elevations determined by **NWaveElev** in the HydroDyn primary input file, such that the total number of wave elevation outputs is  $NWaveElev + (WaveElevNX \times WaveElevNY)$ .

### 4.3 HydroDyn Primary Input File

The HydroDyn input file defines the substructure geometry, hydrodynamic coefficients, incident wave kinematics and current, potential-flow solution options, flooding/ballasting and marine growth, and auxiliary parameters. The geometry of strip-theory members is defined by joint coordinates of the undisplaced substructure in the global reference system, with the origin at the intersection of the undeflected tower centerline with MSL. A member connects two joints; multiple members can use a common joint. The hydrodynamic loads are computed at nodes, which are the resultant of member refinement into multiple (**MDivSize** input) elements (nodes are located at the ends of each element), and they are calculated by the module. Member properties include outer diameter, thickness, and dynamic-pressure, added-mass and viscous-drag coefficients. Member properties are specified at the joints; if properties change from one joint to the other, they will be linearly interpolated for the inner nodes.

The file is organized into several functional sections. Each section corresponds to an aspect of the hydrodynamics model or the submerged substructure.

If this manual refers to an ID in a table entry, this is an integer identifier for the table entry, and these IDs do not need to be consecutive or increasing, but they must be unique for a given table entry. When the text refers to an index, it is referring to a given row in a table. The indexing starts at 1 and increases consecutively down the rows.

A sample HydroDyn primary input file is given in Appendix A.

The input file begins with two lines of header information which is for your use, but is not used by the software. On the next line, set the **Echo** flag to TRUE if you wish to have HydroDyn echo the contents of the HydroDyn input file (useful for debugging errors in the input file). The echo file has the naming convention of *OutRootName.HD.ech*. **OutRootName** is either specified in the HYDRODYN section of the driver input file when running HydroDyn standalone, or by FAST when running a coupled simulation.

#### 4.3.1 Environmental Conditions

**WtrDens** specifies the water density and must be a value greater than or equal to zero; a typical value of seawater is around 1025 kg/m<sup>3</sup>. **WtrDpth** specifies the water depth (depth of the seabed), based on the reference MSL, and must be a value greater than zero. **MSL2SWL** is the offset between the MSL and the still water level (SWL), positive upward. This parameter is useful when simulating the effect of tides or storm-surge sea-level variations without having to alter the substructure geometry information. This parameter must be set to zero if you are using a WAMIT model (**HasWAMIT** = TRUE).

#### 4.3.2 Waves

**WaveMod** specifies the incident wave kinematics model. The options are:

- 0: none = still water
- 1: regular (periodic) waves
- 1P#: regular (periodic) waves with user-specified phase, for example 1P20.0 for regular waves with a 20° phase (without P#, the phase will be random, based on **WaveSeed**); 0° phase represents a cosine function, starting at the peak and decreasing in time
- 2: Irregular waves based on the JONSWAP or Pierson-Moskowitz frequency spectrum
- 3: Irregular waves based on a white-noise frequency spectrum
- 4: Irregular waves based on a user-defined frequency spectrum from routine *UserWaveSpectrm()*; see Appendix D for compiling instructions
- 5: GH Bladed wave data (option has been disabled for this release)

Option 4 requires that the *UserWaveSpectrm()* subroutine of the *Waves.f90* source file be implemented by the user, and will require recompiling either the stand-alone HydroDyn program or FAST. Option 5 requires the availability of several input files, all of which have the root name given by the **GHWvFile** parameter, but the option has been disabled for this release.

This version does not include the ability to model stretching incident wave kinematics to the instantaneous free surface; you must set **WaveStMod** = 0.

**WaveTMax** sets the length of the incident wave kinematics time series, but it also determines the frequency step used in the inverse Fourier transform, from which the time series are derived. If **WaveTMax** is less than the total simulation time, HydroDyn implements repeating wave kinematics that have a period of **WaveTMax**. **WaveDT** determines the time step for the wave

kinematics time series, but it also determines the maximum frequency in the inverse Fourier transform. When modeling irregular sea states, we recommend that **WaveTMax** be set to at least 1 hour (3600 s) and that **WaveDT** be a value in the range between 0.1 and 1.0 s to ensure sufficient resolution of the wave spectrum and wave kinematics. **WaveDT** may be specified arbitrarily independently from the glue code time step of FAST. (The wave kinematics and hydrodynamic loads will be interpolated in time as necessary.)

The wave height for regular waves and the significant wave height for irregular waves is set using **WaveHs**. The wave period for regular waves the peak-spectral wave period for irregular waves is controlled with the **WaveTp** parameter. **WavePkShp** is the peak-shape parameter of JONSWAP irregular wave spectrum. Set **WavePkShp** to DEFAULT to obtain the value recommended in the IEC 61400-3 Annex B, derived based on the peak-spectral period and significant wave height. Set **WavePkShp** to 1.0 for the Pierson-Moskowitz spectrum. **WvLowCOff** and **WvHiCOff** control the lower and upper cut-off frequencies of the wave spectrum; the spectrum is zeroed below and above these cut-off frequencies, respectively.

**WaveDir** is the mean wave propagation heading direction (in degrees), and must be in the range  $(-180, 180]$ . A heading of 0 corresponds to wave propagation in the positive X-axis direction. And a heading of 90 corresponds to wave propagation in the positive Y-axis direction. **WaveDirMod** specifies the wave directional spreading model; **WaveDirMod** = 0 disables directional spreading and **WaveDirMod** = 1 enables the commonly used cosine spreading function ( $\text{COS}^{2S}$ ) to define the directional spreading spectrum, based on the spreading coefficient ( $S$ ) defined via **WaveDirSpread**. The wave directional spreading spectrum is discretized with an equal-energy method using **WaveNDir** number of equal-energy bands (where **WaveNDir** is an odd-valued integer greater or equal to 1). The range of the directional spread (in degrees) is defined via **WaveDirSpread**.

**WaveSeed(1)** and **WavedSeed(2)** combined determine the initial seed (starting point) for the internal pseudorandom number generator needed to derive the wave kinematics from the wave frequency and direction spectra. If you want to run different time-domain realizations for given boundary conditions (of significant wave height, and peak-spectral period, etc.), you should change one or both seeds between simulations. While the phase of each wave frequency and direction component of the wave spectrum is always based on a uniform distribution (except when using the 1P# **WaveMod** option), the amplitude of the wave frequency spectrum can also be randomized (following a normal distribution) by setting **WaveNDamp** to TRUE. Setting **WaveNDamp** to FALSE means that the amplitude of the wave frequency spectrum always matches the target spectrum.

You can generate up to 9 wave elevation outputs. **NWaveElev** determines the number (between 0 and 9), and the whitespace-separated lists of **WaveElevxi** and **WaveElevyi** determine the locations of these **NWaveElev** number of points on the SWL plane in the global inertial-frame coordinate system.

### 4.3.3 2<sup>nd</sup>-Order Waves

The implementation of second-order wave kinematics is ongoing and the associated inputs are not yet documented.

#### 4.3.4 Current

You can include water velocity due to a current model by setting **CurrMod** = 1. If **CurrMod** is set to zero, then the simulation will not include current. **CurrMod** = 2 requires that the *UserCurrent()* subroutine of the *Current.f90* source file be implemented by the user, and will require recompiling either the stand-alone HydroDyn program or FAST.

HydroDyn's standard current model includes three sub-models: near-surface, sub-surface, and depth-independent. All three currents are vector summed, along with the wave particle kinematics velocity.

The sub-surface current model follows a power law,

$$U_{ss}(Z) = U_{0ss} \left( \frac{Z+d}{d} \right)^{\frac{1}{7}},$$

where  $Z$  is the local depth below the SWL (negative downward),  $d$  is the water depth (equal to **WtrDpth** + **MSL2SWL**), and  $U_{0ss}$  is the current velocity at SWL, corresponding to **CurrSSV0**.

The heading of the sub-surface current is defined using **CurrSSDir**, following the same convention as **WaveDir**.

The near-surface current model follows a linear relationship down to a reference depth such that,

$$U_{NS}(Z) = U_{0NS} \left( \frac{Z+h_{ref}}{h_{ref}} \right), Z \in [-h_{ref}, 0] \quad \text{otherwise, } U_{NS}(Z) = 0,$$

where  $h_{ref}$  is the reference depth corresponding to **CurrNSRef**, and must be positive valued.

$U_{0NS}$  is the current velocity at SWL, corresponding to **CurrNSV0**. The heading of the near-surface current is defined using **CurrNSDir**, following the same convention as **WaveDir**. The depth-independent current velocity everywhere equals **CurrDIV**. This current has a heading direction **CurrDIDir**, following the same convention as **WaveDir**.

#### 4.3.5 Floating Platform

This and the next few sections of the input file have "Floating Platform" in the title, but the input parameters control the potential-flow model, regardless of whether the substructure is floating or not.

If the load contributions from potential-flow theory are to be used, set **HasWAMIT** to TRUE and include the root name for the WAMIT-related output files in **WAMITFile**. These files consist of the *.I*, *.3*, and *.hst* files. These are written by the WAMIT program and should not include any file headers. When the linear state-space model is used in placed of convolution, the *.ss* file generated by SS\_Fitting must have the same root name as the other WAMIT-related files (see **RdtnMod** below). If **HasWAMIT** is FALSE, the remaining parameters in this section are ignored.

The output files from WAMIT are in a standard nondimensional form that HydroDyn will dimensionalize internally upon input. **WAMITULEN** is the characteristic body length scale used to redimensionalize the WAMIT output. The body motions and forces in these files are in relation to the WAMIT reference point (WRP) in HydroDyn, which for the undisplaced substructure is the same as the origin of the global inertial-frame coordinate system (0,0,0). The *.hst* file contains the 6x6 linear hydrostatic restoring (stiffness) matrix of the platform. The *.I* file contains the 6x6 frequency-dependent hydrodynamic added-mass and damping matrix of the platform from the radiation problem. The *.3* file contains the 6x1 frequency- and direction-dependent wave-excitation force vector of the platform from the linear diffraction problem. While HydroDyn expects hydrodynamic coefficients derived from WAMIT, if you are not using WAMIT, it is recommended that you reformat your data according to the WAMIT format (including nondimensionalization) before inputting them to HydroDyn. Information on the WAMIT format is available from Chapter 4 of the WAMIT User's Guide [Lee].

**PtfmVol0** is the displaced volume of water when the platform is in its undisplaced position. This value should be set equal to the value computed by WAMIT as output in the WAMIT *.out* file. **PtfmCOBxt** and **PtfmCOByt** are the *X* and *Y* offsets of the center of buoyancy from the WRP.

HydroDyn has two methods for calculating the radiation memory effect. Set **RdtnMod** to 1 for the convolution method, 2 for the linear state-space model, or 0 to disable the memory effect calculation. For the convolution method, **RdtnTMax** determines how long to track the memory effect (truncating the convolutions at  $t - \mathbf{RdtnTMax}$ , where  $t$  is the current simulation time), but it also determines the frequency step used in the cosine transform, from which the time-domain radiation kernel (radiation impulse-response function) is derived. A **RdtnTMax** of 60 s is usually more than sufficient because the radiation kernel decays to zero after a short amount of time; setting **RdtnTMax** much greater than this will cause HydroDyn to run significantly slower. (**RdtnTMax** does not need to match or exceed the total simulation length.) Setting **RdtnTMax** to 0 s disables the memory effect, akin to setting **RdtnMod** to 0. For the convolution method, **RdtnDT** is the time step for the radiation calculations (numerical convolutions), but also determines the maximum frequency in the cosine transform. For the state-space model, **RdtnDT** is the time step to use for time integration of the linear state-space model. In this version of HydroDyn, **RdtnDT** must match the glue code (FAST/driver program) simulation time step; the DEFAULT keyword can be used for this.

#### 4.3.6 2<sup>nd</sup>-Order Floating Platform Forces

The implementation of second-order wave potential-flow hydrodynamic loads is ongoing and the associated inputs are not yet documented.

#### 4.3.7 Floating Platform Force Flags

This release requires that all platform force flags be set to TRUE. Future releases will allow you to turn on/off one or more of the six platform force components.

#### 4.3.8 Platform Additional Stiffness and Damping

The vectors and matrices of this section are used to generate additional loads on the platform (in addition to other hydrodynamic terms calculated by HydroDyn), per the following equation.

$$\vec{F}_{Add} = \vec{F}_0 - [C]\dot{\vec{q}} - [B]\ddot{\vec{q}} - [B_{quad}]ABS(\dot{\vec{q}})\dot{\vec{q}},$$

where  $\vec{F}_0$  corresponds to the **AddF0** 6x1 static load (preload) vector,  $[C]$  corresponds to the **AddCLin** 6x6 linear restoring (stiffness) matrix,  $[B]$  corresponds to the **AddBLin** 6x6 linear damping matrix,  $[B_{quad}]$  corresponds to the **AddBQuad** 6x6 quadratic drag matrix, and  $\vec{q}$  corresponds to the WRP 6x1 (six-DOF) displacement vector (three translations and three rotations), where the overdot refers to the first time-derivative.

These terms can be used, e.g., to model a linearized mooring system, to augment strip-theory members with a linear hydrostatic restoring matrix (see Section 6.6.3), or to “tune” HydroDyn to match damping to experimental results, such as free-decay tests. While likely most useful for floating systems, these matrices can also be used for fixed-bottom systems; in both cases, the resulting load is applied at the WRP, which when HydroDyn is coupled to FAST, get applied to the platform in ElastoDyn (bypassing SubDyn for fixed-bottom systems). See Section 6 for addition modeling considerations where these terms are necessary.

#### 4.3.9 Axial Coefficients

This and the next several sections of the input file control the strip-theory model for both fixed-bottom and floating substructures.

HydroDyn computes lumped viscous-drag, added-mass, fluid-inertia, and static pressure loads at member ends (joints). The hydrodynamic coefficients for the lumped the lumped loads at joints are referred to as “axial coefficients” and include viscous-drag coefficients, **AxCd**, added-mass coefficients, **AxCa**, and dynamic-pressure coefficients, **AxCp**. **AxCa** influences both the added-mass loads and the scattering component of the fluid-inertia loads. Any number of separate axial coefficient sets, distinguished by **AxCoeffID**, may be specified by setting **NAxCoeff** > 1.

Axial viscous-drag loads will be calculated for all specified member joints. Axial added-mass, fluid-inertia, and static-pressure loads will only be calculated for member joints of members not modeled with WAMIT (**PropWAMIT** = FALSE). Axial loads are only calculated at user-specified joints. Axial loads are not calculated at joints HydroDyn may automatically create as part its solution process. For example, if you want axial effects at a marine-growth boundary (where HydroDyn automatically adds a joint), you must explicitly set a joint at that location.

#### 4.3.10 Member Joints

The strip-theory model is based on a substructure composed of joints interconnected by members. **NJoints** is the user-specified number of joints and determines the number of rows in the subsequent table. Because a member connects two nodes, **NJoints** must be exactly zero or greater than or equal to 2. Each joint listed in the table is identified by a unique integer, **JointID**. The (X,Y,Z) coordinate of each joint is specified in the global inertial-frame coordinate system via **Jointxi**, **Jointyi**, and **Jointzi**, respectively. **JointAxID** corresponds to an entry in the AXIAL COEFFICIENTS table and sets the axial coefficients for a joint. This version of HydroDyn cannot calculate joint overlap when multiple members meet at a common joint; therefore **JointOvrp** must be set to 0. Future releases will enable joint overlap calculations.

Modeling a fixed-bottom substructure embedded into the seabed (e.g., through piles or suction buckets) requires that the lowest member joint(s) lie below the water depth. Placing a joint at or above the water depth results in static pressure loads being applied.

#### 4.3.11 Member Cross-Sections

Members in HydroDyn are assumed to be straight circular (and possibly tapered) cylinders. Apart from the hydrodynamic coefficients, the circular cross-section properties needed for the hydrodynamic load calculations are member outer diameter, **PropD**, and member thickness, **PropThick**. You will need to create an entry in this table, distinguished by **PropSetID**, for each unique combination of these two properties. The member property-set table contains **NPropSets** rows. The member property sets are referred to by their **PropSetID** in the MEMBERS table, as described in Section 4.3.13 below. **PropD** determines the static buoyancy loads exterior to a member, as well as the area used in the viscous-drag calculation and the volume used in the added-mass and fluid-inertia calculations. **PropThick** determines the interior volume for fluid-filled (flooded/ballasted) members.

#### 4.3.12 Hydrodynamic Coefficients

HydroDyn computes distributed viscous-drag, added-mass, fluid-inertia, and static buoyancy loads along members.

The hydrodynamic coefficients for the distributed strip-theory loads are specified using any of three models, which we refer to as the simple model, a depth-based model, and a member-based model. All of these models require the specification of both transverse and axial hydrodynamic coefficients for viscous drag, added mass, and dynamic pressure (axial viscous drag is not yet available). The added-mass coefficient influences both the added-mass loads and the scattering component of the fluid-inertia loads. There are separate set of hydrodynamic coefficients both with and without marine growth. A given element will either use the marine growth or the standard version of a coefficient, but never both. Note that input members are split into elements per Section 7.5.2, one of the splitting rules guarantees the previous statement is true. Which members have marine growth is defined by the MARINE GROWTH table of Section 4.3.15. You can specify only one model type, **MCoeffMod**, for any given member in the MEMBERS table. However, different members can specify different coefficient models.

In the hydrodynamic coefficient input parameters,  $C_d$ ,  $C_a$ , and  $C_p$  refer to the viscous-drag, added-mass, and dynamic-pressure coefficients, respectively,  $MG$  identifies the coefficients to be applied for members with marine growth (the standard values are identified without  $MG$ ), and  $Ax$  identifies the axial coefficients to be applied for tapered members (the transverse coefficients are identified without  $Ax$ ). It is noted that for the transverse coefficients,  $C_p + C_a = C_M$ , the inertia coefficient.

While the strip-theory solution assumes circular cross sections, the hydrodynamic coefficients can include shape corrections; however, there is no distinction made in HydroDyn between different transverse directions.

#### 4.3.12.1 Simple Model

This table consists of a single complete set of hydrodynamic coefficients as follows: *SimplCd*, *SimplCdMG*, *SimplCa*, *SimplCaMG*, *SimplCp*, *SimplCpMG*, *SimplAxCa*, *SimplAxCaMG*, *SimplAxCp*, and *SimplAxCpMG*. These hydrodynamic coefficients are referenced in the members table of Section 4.3.13 by selecting *MCoefMod* = 1.

#### 4.3.12.2 Depth-Based Model

The depth-based coefficient model allows you to specify a series of depth-dependent coefficients. *NCoefDpth* is the user-specified number of depths and determines the number of rows in the subsequent table. Currently, this table requires that the rows are ordered by increasing depth, *Dpth*; this is equivalent to a decreasing global Z-coordinate. The hydrodynamic coefficients at each depth are as follows: *DpthCd*, *DpthCdMG*, *DpthCa*, *DpthCaMG*, *DpthCp*, *DpthCpMG*, *DpthAxCa*, *DpthAxCaMG*, *DpthAxCp*, and *DpthAxCpMG*. Members use these hydrodynamic coefficients by setting *MCoefMod* = 2. The HydroDyn module will interpolate coefficients for a node whose Z-coordinate lies between table Z-coordinates.

#### 4.3.12.3 Member-Based Model

The member-based coefficient model allows you to specify a hydrodynamic coefficients for each particular member. *NCoefMembers* is the user-specified number of members with member-based coefficients and determines the number of rows in the subsequent table. The hydrodynamic coefficients for a member distinguished by *MemberID* are as follows: *MemberCd1*, *MemberCd2*, *MemberCdMG1*, *MemberCdMG2*, *MemberCa1*, *MemberCa2*, *MemberCaMG1*, *MemberCaMG2*, *MemberCp1*, *MemberCp2*, *MemberCpMG1*, *MemberCpMG2*, *MemberAxCa1*, *MemberAxCa2*, *MemberAxCaMG1*, *MemberAxCaMG2*, *MemberAxCp1*, *MemberAxCp2*, *MemberAxCpMG1*, and *MemberAxCpMG2*, where 1 and 2 identify the starting and ending joint of the member, respectively. Members use these hydrodynamic coefficients by setting *MCoefMod* = 3.

### 4.3.13 Members

*NMembers* is the user-specified number of members and determines the number of rows in the subsequent table. For each member distinguished by *MemberID*, *MJointID1* specifies the starting joint and *MJointID2* specifies the ending joint, corresponding to an identifier (*JointID*) from the MEMBER JOINTS table. Likewise, *MPropSetID1* corresponds to the starting cross-section properties and *MProSetID2* specify the ending cross-section properties, allowing for tapered members. *MDivSize* determines the maximum spacing (in meters) between simulation nodes where the distributed loads are actually computed; the smaller the number, the finer the resolution and longer the computational time. Section 7.5.2 discusses the difference between the user-supplied discretization and the simulation discretization. Each member in your model will have hydrodynamic coefficients, which are specified using one of the three models (*MCoefMod*). Model 1 uses a single set of coefficients found in the SIMPLE HYDRODYNAMIC COEFFICIENTS section. Model 2 is depth-based, and is determined via the table found in the DEPTH-BASED HYDRODYNAMIC COEFFICIENTS section. Model 3 specifies coefficients for a particular member, by referring to the MEMBER-BASED HYDRODYNAMIC COEFFICIENTS section. The *PropWAMIT* flag indicates whether the corresponding member coincides with the body represented by the potential-flow solution.

When **PropWAMIT** = TRUE, only viscous-drag loads, and ballasting loads will be computed for that member.

#### 4.3.14 Filled Members

Members—whether they are also modeled with potential-flow or not—may be fluid-filled, meaning that they are flooded and/or ballasted. Fluid-filled members introduce interior buoyancy that subtracts from the exterior buoyancy and a mass. Both distributed loads along a member and lumped loads at joints are applied. The volume of fluid in the member is derived from the outer diameter and thickness of the member and a fluid-filled free-surface level. The fluid in the member is assumed to be compartmentalized such that it does not slosh. Rotational inertia of the fluid in the member is ignored. A member's filled configuration is defined by the filled-fluid density and the free-surface level. Filled members that have the same configuration are collected into fill groups.

**NFillGroups** specifies the number of fluid-filled member groups and determines the number of rows in the subsequent table. **FillNumN** specifies the number of members in the fill group. **FillMList** is a list of **FillNumN** whitespace-separated **MemberIDs**. **FillFSLoc** specifies the Z-height of the free-surface (0 for MSL). **FillDens** is the density of the fluid. If **FillDens** = DEFAULT, then **FillDens** = **WtrDens**.

#### 4.3.15 Marine Growth

Members not also modeled with potential-flow theory may be modeled with marine growth. Marine growth causes three effects. First, marine growth introduces a static weight and mass to a member, applied as distributed loads along the member. Second, marine growth increases the outer diameter of a member, which impacts the diameter used in the viscous-drag, added-mass, fluid-inertia, and static buoyancy load calculations. Third, the hydrodynamic coefficients for viscous drag, added mass, and dynamic pressure are specified distinctly for marine growth. Rotational inertia of the marine growth is ignored and marine growth is not added to member ends.

Marine growth is specified using a depth-based table with **NMGDepths** rows. This table must have exactly zero or at least 2 rows. The columns in the table include the local depth, **MGDpth**, the marine growth thickness, **MGThck**, and marine growth density, **MGDens**. Marine growth for a particular location in the substructure geometry is added by linearly interpolating between the marine-growth table entries. The smallest and largest values of **MGDpth** define the marine growth region. Outside this region the marine growth thickness is set to zero. If you want sub-regions of zero marine growth thickness within these bounds, you must generate depth entries which explicitly set **MGThck** to zero. The hydrodynamic coefficient tables contain coefficients with and without marine growth. If **MGThck** = 0 for a particular node, the coefficients not associated with marine growth are used.

#### 4.3.16 Member Output List

HydroDyn can output distributed load and wave kinematic quantities at up to 9 locations on up to 9 different members, for a total of 81 possible local member output locations. **NMOutputs** specifies the number of members. You must create a table entry for each requested member. Within a table entry, **MemberID** is the ID specified in the MEMBERS table, and **NOutLoc**

specifies how many output locations are generated for this member. **NodeLocs** specifies those locations as a normalized distance from the starting joint (0.0) to the ending joint (1.0) of the member. If the chosen location does not align with a calculation node, the results at the two surrounding nodes will be linearly interpolated. The outputs specified in the OUTPUT CHANNELS section determines which quantities are actually output at these locations.

#### 4.3.17 Joint Output List

HydroDyn can output lumped load and wave kinematic quantities at up to 9 different joints. **JOutLst** contains a list of **NJOutputs** number of **JointIDs**. The outputs specified in the OUTPUT CHANNELS section determines which quantities are actually output at these joints.

#### 4.3.18 Output

Specifying **HDSum** = TRUE causes HydroDyn to generate a summary file with name **OutRootname.HD.sum**. **OutRootName** is either specified in the HYDRODYN section of the driver input file when running HydroDyn standalone, or by the FAST program when running a coupled simulation. See section 5.3 for summary file details.

For this version, **OutAll** must be set to FALSE. In future versions, setting **OutAll** = TRUE will cause HydroDyn to auto-generate outputs for every joint and member in the input file.

If **OutSwitch** is set to 1, outputs are sent to a file with the name **OutRootname.HD.out**. If **OutSwitch** is set to 2, outputs are sent to the calling program (FAST) for writing. If **OutSwitch** is set to 3, both file outputs occur.

The **OutFmt** and **OutSFmt** parameters control the formatting for the output data and the channel headers, respectively. HydroDyn currently does not check the validity of these format strings. They need to be valid Fortran format strings. Since the **OutSFmt** is used for the column header and **OutFmt** is for the channel data, in order for the headers and channel data to align properly, the width specification should match. For example,

```
"ES11.4"      OutFmt
"A11"         OutSFmt
```

#### 4.3.19 Output Channels

This section controls output quantities generated by HydroDyn. Enter one or more lines containing quoted strings that in turn contain one or more parameter names. Separate output parameter names by any combination of commas, semicolons, spaces, and/or tabs. If you prefix a parameter name with a minus sign, “-”, underscore, “\_”, or the characters “m” or “M”, HydroDyn will multiply the value for that channel by -1 before writing the data. The parameters are written in the order they are listed in the input file. HydroDyn allows you to use multiple lines so that you can break your list into meaningful groups and so the lines can be shorter. You may enter comments after the closing quote on any of the lines. Entering a line with the string “END” at the beginning of the line or at the beginning of a quoted string found at the beginning of the line will cause HydroDyn to quit scanning for more lines of channel names. Member- and joint-related quantities are generated for the requested MEMBER OUTPUT LIST and JOINT OUTPUT LIST. If HydroDyn encounters an unknown/invalid channel name, it warns the users

but will remove the suspect channel from the output file. Please refer to Appendix C for a complete list of possible output parameters.

## 5 Output Files

HydroDyn produces four types of output files: an echo file, a wave-elevations file, a summary file, and a time-series results file. The following sections detail the purpose and contents of these files.

### 5.1 Echo Files

If you set the **Echo** flag to TRUE in the HydroDyn driver file or the primary HydroDyn input file, the contents of those files will be echoed to a file with the naming conventions, *OutRootName.dvr.ech* for the driver input file and *OutRootName.HD.ech* for the primary HydroDyn input file. **OutRootName** is either specified in the HYDRODYN section of the driver input file, or by the FAST program. The echo files are helpful for debugging your input files. The contents of an echo file will be truncated if HydroDyn encounters an error while parsing an input file. The error usually corresponds to the line after the last successfully echoed line.

### 5.2 Wave-Elevations File

Setting **WaveElevSeriesFlag** in the driver file to TRUE enables the outputting of a grid of wave elevations to a text-based file with the name *OutRootName.WaveElev.out*. The grid consists of **WaveElevNX** by **WaveElevNY** wave elevations (centered at  $X=0$ ,  $Y=0$ ) with a  $dX$  and  $dY$  spacing in the global inertial-frame coordinate system. These wave elevations are distinct and output separately from the wave elevations determined by **NWaveElev** in the HydroDyn primary input file, such that the total number of wave elevation outputs is  $NWaveElev + (WaveElevNX \times WaveElevNY)$ .

### 5.3 Summary File

HydroDyn generates a summary file with the naming convention, *OutRootName.HD.sum* if the **HDSum** parameter is set to TRUE. This file summarizes key information about your hydrodynamics model, including buoyancy, substructure volumes, marine growth weight, the simulation mesh and its properties, wave kinematics, and the radiation kernel.

#### 5.3.1 WAMIT-model volume and buoyancy information

This section summarizes the buoyancy of the potential-flow-model platform in its undisplaced configuration. For a hybrid potential-flow/strip-theory model, these buoyancy values must be added to any strip-theory member buoyancy reported in the subsequent sections to obtain the total buoyancy of the platform.

#### 5.3.2 Substructure Volume Calculations

This section contains a summary of the total substructure volume, the submerged volume, volume of any marine growth, and fluid-filled (flooded/ballasted) volume for the substructure in its undisplaced configuration. Except for the fluid-filled volume value, the reported volumes are only for members that have the **PropWAMIT** flag set to FALSE. The flooded/ballasted volume applies to any fluid-filled member, regardless of its **PropWAMIT** flag.

#### 5.3.3 Integrated Buoyancy Loads

This section details the buoyancy loads of the undisplaced substructure when summed about the WRP (0,0,0). The external buoyancy includes the effects of marine growth, and only applies to

members whose **PropWAMIT** flag is set to FALSE. The internal buoyancy is the negative effect on buoyancy due to flooding or ballasting and is independent of the **PropWAMIT** flag.

### 5.3.4 Integrated Marine Growth Weights

This section details the marine growth weight loads of the undisplaced substructure when summed about the WRP (0,0,0).

### 5.3.5 Simulation Node Table

This table details the undisplaced nodal information and properties for the simulation mesh. The node index is provided in the first column. The second column maps the node to the input joint index (not to be confused with the **JointID**). If a value of -1 is found in this column, the node is an interior node and results from an input member being split somewhere along its length due to the requirements of the **MDivSize** parameter in the primary input file members table. See Section 7.5.2 for the member splitting rules used by HydroDyn. The third column indicates if this node is part of a Super Member (**JointOvrtp** = 1). The next column tells you the corresponding input member index (not to be confused with the **MemberID**). **Nxi**, **Nyi**, and **Nzi**, provide the (X,Y,Z) coordinates in the global inertial-frame coordinate system. **InpMbrDist** provides the normalized distance to the node from the start of the input member. **R** is the outer radius of the member at the node (excluding marine growth), and **t** is the member wall thickness at the node. **dRdZ** is the taper of the member at the node, **tMG** is the marine growth thickness, and **MGDens** is the marine growth density. **PropWAMIT** indicates whether the element attached to this node is modeled using potential-flow theory. If **FilledFlag** is TRUE, then **FillDens** gives the filled fluid density and **FillFSLoc** indicates the free-surface height (Z-coordinate). **Cd**, **Ca**, **Cp**, **AxCa**, **AxCp**, **JACd**, **JACa**, and **JACp** are the viscous-drag, added-mass, dynamic-pressure, axial added-mass, axial dynamic-pressure, end-effect axial viscous-drag, end-effect axial added-mass, and end-effect axial dynamic-pressure coefficients, respectively. **NConn** gives the number of elements connected to node, and **Connection List** is the list of element indexes attached to the node.

### 5.3.6 Simulation Element Table

This section details the undisplaced simulation elements and their associated properties. A suffix of 1 or 2 in a column heading refers to the element's starting or ending node, respectively. The first column is the element index. **node1** and **node2** refer to the node index found in the node table of the previous section. Next are the element **Length** and exterior **Volume**. This exterior volume calculation includes any effects of marine growth. **MGVolume** provides the volume contribution due to marine growth. The cross-sectional properties of outer radius (excluding marine growth), marine growth thickness, and wall thickness for each node are given by **R1**, **tMG1**, **t1**, **R2**, **tMG2**, and **t2**, respectively. **MGDens1** and **MGDens2** are the marine growth density at node 1 and 2. **PropWAMIT** indicates if the element is modeled using potential-flow theory. If the element is fluid-filled (has flooding or ballasting), **FilledFlag** is set to **T** for TRUE. **FillDensity** and **FillFSLoc** are the filled fluid density and the free-surface location's Z-coordinate in the global inertial-frame coordinate system. **FillMass** is calculated by multiplying the **FillDensity** value by the element's interior volume. Finally, the element hydrodynamic coefficients are listed. These are the same coefficients listed in the node table (above).

### 5.3.7 Summary of User-Requested Outputs

The summary file includes information about all requested member and joint output channels.

#### 5.3.7.1 Member Outputs

The first column lists the data channel's string label, as entered in the OUTPUT CHANNELS section of the HydroDyn input file.  $X_i$ ,  $Y_i$ ,  $Z_i$ , provide the output's undisplaced spatial location in the global inertial-frame coordinate system. The next column, *InpMbrIndx*, tells you the corresponding input member index (not to be confused with the *MemberID*). Next are the coordinates of the starting (*StartXi*, *StartYi*, *StartZi*) and ending (*EndXi*, *EndYi*, *EndZi*) nodes of the element containing this output location. *Loc* is the normalized distance from the starting node of this element.

#### 5.3.7.2 Joint Outputs

The first column lists the data channel's string label, as entered in the OUTPUT CHANNELS section of the HydroDyn input file.  $X_i$ ,  $Y_i$ ,  $Z_i$ , provide the output's undisplaced spatial location in the global inertial-frame coordinate system. *InpJointID* specifies the *JointID* for the output as given in the MEMBER JOINTS table of the HydroDyn input file.

### 5.3.8 The Wave Number and Complex Values of the Wave Elevations as a Function of Frequency

This section provides the frequency-domain description (in terms of a Discrete Fourier Transform or DFT) of the wave elevation at (0,0) on the free surface. The first column,  $m$ , identifies the index of each wave frequency component. The finite-depth wave number, frequency, and direction of the wave component are given by  $k$ ,  $\Omega$ , and *Direction*, respectively. The last two columns provide the real ( $REAL(DFT\{WaveElev\})$ ) and imaginary ( $IMAG(DFT\{WaveElev\})$ ) components of the DFT of the wave elevation. The DFT produces includes both the negative- and positive-frequency components. The negative-frequency components are complex conjugates of the positive frequency components because the time-domain wave elevation is real-valued. The relationships between the negative- and positive-frequency components of the DFT are given by  $k(-\omega) = -k(\omega)$  and  $H(-\omega) = H(\omega)^*$ , where  $H$  is the DFT of the wave elevation and  $*$  denotes the complex conjugate.

### 5.3.9 Radiation Memory Effect Convolution Kernel

HydroDyn computes the radiation kernel used by the convolution method for calculating the radiation memory effect through the cosine transform of the 6x6 frequency-dependent hydrodynamic damping matrix from the radiation problem. The resulting time-domain radiation kernel (radiation impulse-response function)—which is a 6x6 time-dependent matrix—is provided in this section.  $n$  and  $t$  give the time-step index and time, which are followed by the elements ( $K11$ ,  $K12$ , etc.) of the radiation kernel associated with that time. Because the frequency-dependent hydrodynamic damping matrix is symmetric, so is the radiation kernel; thus, only the diagonal and upper-triangular portion of the matrix are provided. The radiation kernel should decay to zero after a short amount of time, which should aid in selecting an appropriate value of *RdtnTMax*.

## 5.4 Results File

The HydroDyn time-series results are written to a text-based file with the naming convention *OutRootName.HD.out* when ***OutSwitch*** is set to either 1 or 3. If HydroDyn is coupled to FAST and ***OutSwitch*** is set to 2 or 3, then FAST will generate a master results file that includes the HydroDyn results. The results are in table format, where each column is a data channel, and each row corresponds to a simulation time step. The data channels are specified in the OUTPUT CHANNELS section of the input file. The column format of the HydroDyn-generated file is specified using the ***OutFmt*** and ***OutSFmt*** parameter of the input file.

## 6 Modeling Considerations

HydroDyn was designed as an extremely flexible tool for modeling a wide-range of hydrodynamic conditions and substructures. This section provides some general guidance to help you construct models that are compatible with HydroDyn.

Please refer to the theory of Section 7 for detailed information about HydroDyn's coordinate systems, and the implementation approach we have followed in HydroDyn.

### 6.1 Strip-Theory Model Discretization

A user will define the geometry of a structure modeled with strip theory in HydroDyn using joints and members. Those members can be further subdivided using ***MDivSize***, which HydroDyn will internally use to subdivide members into multiple elements (and nodes). HydroDyn may further refine the geometry at the free surface, seabed, marine-growth region, and filled-fluid free surface. The rules HydroDyn uses for refinement may be found in Section 7.5.2.

Due to the exponential decay of hydrodynamic loads with depth, HydroDyn requires higher resolution near the water free surface to capture hydrodynamic loading as waves oscillate about the still water level (SWL). It is recommended, for instance, that the HydroDyn discretization not exceed element lengths of 0.5 m in the region of the free surface (5 to 10 m above and below SWL), 1.0 m between 25 and 50 m depth, and 2.0 m in deeper waters. When HydroDyn is coupled to SubDyn through FAST for the analysis of fixed-bottom systems, it is recommended that the length ratio between elements of HydroDyn and SubDyn not exceed 10 to 1.

Members in HydroDyn are assumed to be straight circular (and possibly tapered) cylinders. While the strip-theory solution assumes circular cross sections, the hydrodynamic coefficients can include shape corrections; however, there is no distinction made in HydroDyn between different transverse directions.

### 6.2 Domain for Hydrodynamic Load Calculations

Part of the automated geometry refinement mentioned in the above section deals with splitting of input members into sub-elements such that both of the resulting nodes at the element ends lie within the discrete domains described in the following sections.

#### 6.2.1 Distributed Loads

##### 6.2.1.1 *Inertia, Added Mass, Buoyancy, Marine-Growth Weight, Marine-Growth Mass Inertia*

These loads are generated at a node as long as ***PropWAMIT*** = FALSE, the Z-coordinate is in the range  $[-WtrDpth, MSL2SWL]$ , and the element the node is connected to is in the water.

##### 6.2.1.2 *Filled Buoyancy, Filled Mass Inertia*

These loads are generated at a node as long as the Z-coordinate is in the range  $[-WtrDpth, FillFSLoc]$  and the element the node is connected to is in the filled fluid.

### 6.2.1.3 Viscous Drag

These loads are generated at a node as long as the Z-coordinate is in the range  $[-WtrDpth, MSL2SWL]$  and the element the node is connected to is in the water.

### 6.2.2 Lumped Loads

Lumped loads at member ends (axial effects) are only calculated at user-specified joints, and not at joints HydroDyn may automatically create as part its solution process (see Section 7.5.2 for differences between the input-file discretization and the simulation discretization). For example, if you want axial effects at a marine-growth boundary, you must explicitly set a joint at that location.

#### 6.2.2.1 Added Mass, Inertia, Buoyancy

These loads are generated at a node as long as **PropWAMIT** = FALSE and the Z-coordinate is in the range  $[-WtrDpth, MSL2SWL]$ .

#### 6.2.2.2 Axial Drag

These loads are generated at a node as long as the Z-coordinate is in the range  $[-WtrDpth, MSL2SWL]$ .

#### 6.2.2.3 Filled Buoyancy

These loads are generated at a node as long as the Z-coordinate is in the range  $[-WtrDpth, FillFSLoc]$

## 6.3 Impact of Substructure Motions on Loads

In general, HydroDyn assumes that structural motions of the substructure are small, such that (1) small-angle assumptions apply to structural rotations, (2) the potential-flow solution can be split into uncoupled hydrostatic, radiation, and diffraction solutions, and (3) the hydrodynamic loads dependent on wave kinematics (both from diffraction loads in the potential-flow solution and from the fluid-inertia and viscous-drag loads in the strip-theory solution) can be computed using wave kinematics solved at the undisplaced position of the substructure (the wave kinematics are not recomputed at the displaced position). Nevertheless, HydroDyn uses the substructure motions in the following calculations:

- The structural displacements of the WRP are used in the calculation of the hydrostatic loads (i.e., the change in buoyancy with substructure displacement) in the potential-flow solution.
- The structural velocities and accelerations of the WRP are used in the calculation of the wave-radiation loads (i.e., the radiation memory effect and added mass) in the potential-flow solution.
- The structural displacements and velocities of the WRP are used in the calculation of the additional platform loads (via the Platform Additional Stiffness and Damping).
- The structural velocities of the substructure nodes are used in the calculation of the viscous-drag loads in the strip-theory solution (e.g., the relative form of Morison's equation is applied).

- The structural accelerations of the substructure nodes are used in the calculation of the added-mass, marine-growth mass inertia, and filled-fluid mass inertia loads in the strip-theory solution.
- When coupled to FAST, the hydrodynamic loads computed by HydroDyn are applied to the displaced position of the substructure (i.e., the displaced platform in ElastoDyn and/or the displaced substructure in SubDyn), but are based on wave kinematics at the undisplaced position.

## 6.4 Platform Additional Stiffness and Damping

HydroDyn allows the user to apply additional loads to the platform (in addition to other hydrodynamic terms calculated by HydroDyn), by including a 6x1 static load vector (preload) (*AddF0*), a 6x6 linear restoring matrix (*AddCLin*), a 6x6 linear damping matrix (*AddBLin*), and a 6x6 quadratic drag matrix (*AddBQuad*). These terms can be used, e.g., to model a linearized mooring system, to augment strip-theory members with a linear hydrostatic restoring matrix (see Section 6.6.3), or to “tune” HydroDyn to match damping to experimental results, such as free-decay tests. While likely most useful for floating systems, these matrices can also be used for fixed-bottom systems; in both cases, the resulting load is applied at the WRP, which when HydroDyn is coupled to FAST, get applied to the platform in ElastoDyn (bypassing SubDyn for fixed-bottom systems).

## 6.5 Fixed-Bottom Substructures

When modeling a fixed-bottom system, the use of a strip-theory (Morison) only model is recommended.

All members which are embedded into the seabed (e.g., through piles or suction buckets) must have a joint that is located below the water depth. For example, if the water depth is set to 20 m, and you are modeling a fixed-bottom monopile, then the bottom-most joint needs to have a Z-coordinate such that  $Z < -20$  m. This configuration avoids having HydroDyn apply static pressure loads on the bottom of the structure.

Gravity-based foundations should be modeled such that the lowest joint(s) are located exactly at the prescribed water depth. In other words, the lowest Z-coordinate should be set to  $Z = -20$  m if the water depth is set to 20 m. This configuration allows for static pressure loads to be applied at the bottom of the gravity-base structure.

## 6.6 Floating Platforms

When modeling a floating system, you may use potential-flow theory (via a WAMIT preprocess) only, strip-theory (Morison) only, or a hybrid model containing both.

Potential-flow theory is enabled when *HasWAMIT* is set to TRUE. In this case, HydroDyn will look for WAMIT input files—see Section 6.6.4 for guidance. For a potential-flow-only model, do not create any strip-theory joints or members in the input file. The WAMIT model should account for all of the members in the floating substructure, and Morison’s equation is neglected in this case.

For a strip-theory-only model, set **HasWAMIT** to FALSE and create one or more strip-theory members in the input file. Marine growth and nonzero **MSL2SWL** (the offset between still-water and mean-sea level) may only be included in strip-theory-only models.

A hybrid model is formed when both **HasWAMIT** is TRUE and you have defined one or more strip-theory members. The WAMIT model created can consider all of the Morison members in the floating substructure, or just some. Specify whether certain members of the structure are considered in the WAMIT model by setting the **PropWAMIT** flag for each member. As detailed in Section 7.5.1, the state of the **PropWAMIT** flag for a given member determines which components of the strip-theory equations are applied.

When using either the strip-theory-only or hybrid approaches, filled fluid (flooding or ballasting) may be added to the strip-theory members. Also, the hydrostatic restoring matrix must be entered manually for the strip-theory members—see Section 6.6.3 for guidance.

### 6.6.1 Undisplaced Position for Floating Systems

The HydroDyn model (geometry, etc.) is defined about the undisplaced position of the substructure. For floating systems, it is important for solution accuracy for the undisplaced position to coincide with the static-equilibrium position in the platform-heave (vertical) direction in the absence of loading from wind, waves, and current. As such, the undisplaced position of the substructure should be defined such that the external buoyancy from displaced water balances with the weight of the system (including the weight of the rotor-nacelle assembly, tower and substructure) and mooring system pretension following the equation below. In this equation,  $\rho$  is the water density,  $g$  is gravity,  $V_0$  is the undisplaced volume of the floating platform (found in the HydroDyn summary file),  $m_{Total}$  is the total mass of the system (found in the ElastoDyn summary), and  $T_{Mooring}$  is the mooring system pretension (found in e.g. the MAP summary file). The effects of marine growth, filled fluid (flooding and/or ballasting), and the additional static force (**AddFX0**) should also be taken into consideration in this force balance, where appropriate.

$$\rho g V_0 - m_{Total} g - T_{Mooring} = 0$$

### 6.6.2 Initial Conditions for Floating Systems

Because the initial conditions used for dynamic simulations typically have an effect on the response statistics during the beginning of the simulation period, an appropriate amount of initial data should be eliminated from consideration in any post-processing analysis. This initial condition solution is more important for floating offshore wind turbines because floating systems typically have long natural periods of the floating substructure and low damping. The appropriate time to eliminate should be chosen such that initial numeric transient effects have sufficiently decayed and the floating substructure has reached a quasi-stationary position. To decrease this initial time in each simulation, it is suggested that the initial conditions of the model (especially blade-pitch angle, rotor speed, substructure surge, and substructure pitch in ElastoDyn) be initialized according to the specific prevalent wind, wave, current, and operational conditions.

### 6.6.3 Hydrostatic Restoring for Strip-Theory Members of Floating Systems

One notable absence from the list calculations in HydroDyn that make use of substructure motions—see Section 6.3—is that the substructure buoyancy in the strip-theory solution is not recomputed based on the displaced position of the substructure. While the change in buoyancy is likely negligible for fixed-bottom systems, for floating systems modeled using a strip-theory solution, the change in buoyancy with displacement is likely important and should not be neglected. In this latter case, the user should manually calculate the 6x6 linear hydrostatic restoring matrix associated with the strip-theory members and enter this as the additional linear restoring (stiffness) matrix, **AddCLin**. (The static buoyancy of the strip-theory members is automatically calculated and applied within HydroDyn.)

In its most general form, the 6x6 linear hydrostatic restoring matrix of a floating platform is given by the equation below.

$$AddCLin = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & \rho g A_0 & \rho g \iint_{A_0} y dA & -\rho g \iint_{A_0} x dA & 0 \\ 0 & 0 & \rho g \iint_{A_0} y dA & \rho g \iint_{A_0} y^2 dA + \rho g V_0 z_b - m_{mg} g z_{mg} - m_f g z_f & -\rho g \iint_{A_0} x y dA & -\rho g V_0 x_b + m_{mg} g x_{mg} + m_f g x_f \\ 0 & 0 & -\rho g \iint_{A_0} x dA & -\rho g \iint_{A_0} x y dA & \rho g \iint_{A_0} x^2 dA + \rho g V_0 z_b - m_{mg} g z_{mg} - m_f g z_f & -\rho g V_0 y_b + m_{mg} g y_{mg} + m_f g y_f \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix},$$

where:

- $\rho$  water density, kg/m<sup>3</sup>
- $g$  gravity, m/s<sup>2</sup>
- $A_0$  undisplaced waterplane area of platform, m<sup>2</sup>
- $V_0$  undisplaced volume of platform, m<sup>3</sup>
- $(x_b, y_b, z_b)$  coordinates of the center of buoyancy of the undisplaced platform, m
- $m_{mg}$  total mass of marine growth, kg
- $(x_{mg}, y_{mg}, z_{mg})$  coordinates of the center of mass of the undisplaced marine growth mass, m
- $m_f$  total mass of ballasting/flooding, kg
- $(x_f, y_f, z_f)$  coordinates of the center of mass of the undisplaced filled fluid (flooding or ballasting) mass, m

The equation above can be simplified when the floating platform has one or more planes of symmetry. That is,  $\iint_{A_0} y dA = 0$ ,  $\iint_{A_0} x y dA = 0$ ,  $y_b = 0$ ,  $y_{mg} = 0$ , and  $y_f = 0$  if the  $x-z$  plane of the platform is a symmetry plane. Likewise,  $\iint_{A_0} x dA = 0$ ,  $\iint_{A_0} x y dA = 0$ ,  $x_b = 0$ ,  $x_{mg} = 0$ , and  $x_f = 0$  if the  $y-z$  plane of the platform is a symmetry plane.

The undisplaced coordinates of the center of buoyancy,  $(x_b, y_b, z_b)$ , center of marine-growth mass,  $(x_{mg}, y_{mg}, z_{mg})$ , and center of filled-fluid mass,  $(x_f, y_f, z_f)$ , are in the global inertial-frame coordinate system. Most of these parameters can be derived from data found in the HydroDyn

summary file. While the equation above makes use of several area integrals, the integrals can often be easily estimated by hand for platforms composed of one or more circular members piercing the waterplane (still-water free surface).

The waterplane area of the undisplaced platform,  $A_0$ , affects the hydrostatic load because the displaced volume of the fluid changes with changes in the platform displacement. Similarly, the location of the center of buoyancy of the platform affects the hydrostatic load because its vector position changes with platform displacement and because the cross product of the buoyancy force with the vector position produces hydrostatic moments about the WRP.  $A_0$ ,  $V_0$ , and  $(x_b, y_b, z_b)$  should be based on the external volume of the platform, including marine-growth thickness. The marine-growth mass and filled-fluid mass also have a direct effect of the hydrostatic restoring because of the moments produced about the WRP.

In classical marine hydrostatics, the effects of body weight are often lumped with the effects of hydrostatics when defining the hydrostatic-restoring matrix; for example, when it is defined in terms of metacentric heights. However, when HydroDyn is coupled to FAST, the body-weight terms (other than the marine-growth and filled-fluid mass within HydroDyn) are automatically accounted for by ElastoDyn, and so, are not included here.

#### 6.6.4 Floating Systems Modeled with Potential Flow

For a potential-flow approach, an external pre-processing tool is needed to generate the appropriate frequency-dependent hydrodynamic coefficients for this model. The naming in this manual has focused on WAMIT, but other frequency-domain wave-body interaction panel codes can be used that produce similar information. However, in the end, the WAMIT format is what is expected by FAST. Therefore, one must create a *.I*, *.3*, and *.hst* file as defined by the WAMIT manual [Lee]. These are automatically created if using WAMIT. When creating these files, one should keep in mind:

- The *.I* file must contain the added-mass matrix at infinite frequency (period = zero).
- The *.I* file must contain the damping matrix over a large range from low frequency to high frequency (the damping should approach zero at both ends of the range). A range of 0.0 to 5.0 rad/s is recommended in most cases.
- The *.3* file must contain the wave-excitation forces across frequencies and directions where there is wave energy. A range of 0.0 to 5.0 rad/s is recommended in most cases and the direction should be specified across the range (-180 to 180] degrees.

An important thing to keep in mind is that the pitch and roll restoring of a floating body depends on the vertical distance between the center of buoyancy and center of mass of the body. In WAMIT, the vertical center of gravity (VCG) is also used to determine the pitch and roll restoring associated with platform weight, and WAMIT will include these effects in the restoring matrix that it outputs (the *.hst* file). However, the ElastoDyn module of FAST intrinsically accounts for the platform weight's influence on the pitch and roll restoring if the platform weight and center-of-mass location are defined appropriately. To avoid double booking these terms, it is important to neglect these terms in WAMIT. This can be achieved by setting VCG to zero in WAMIT.

## 7 HydroDyn Theory

*This is a preliminary draft of the HydroDyn theory and should be considered a work in progress.*

Hydrodynamics are modeled using a suitable combination of incident-wave kinematics and hydrodynamic loading models. Hydrodynamic loads result from the integration of the dynamic pressure of the water over the wetted surface of a floating platform. These loads include contributions from inertia (added mass) and linear drag (radiation), buoyancy (restoring), incident-wave scattering (diffraction), sea current, and nonlinear effects.

### 7.1 Coordinate Systems

#### 7.1.1 Global coordinate system: $(X, Y, Z)$

- The global axes are represented by the unit vectors  $\hat{i}$ ,  $\hat{j}$ , and  $\hat{k}$ .
- The origin is set at the mean sea level, the center of the structure, with Z axis positive upward.
- The positive X axis is along the nominal (zero-degree) wave propagation direction.
- The Y axis can be found assuming a right-handed Cartesian coordinate system.

### 7.1.2 Structural member local coordinate system: $(x, y, z)$

- Axes are represented by the unit vectors  $\hat{i}$ ,  $\hat{j}$ , and  $\hat{k}$ .
- The origin is set at the center of the structural member.
- The local  $z$  axis is along the cylinder axis, directed from the start joint to the end joint. The start joint is defined as the joint that has a lower  $Z$  coordinate value. If the two joints have the same  $Z$  coordinate value, then the one that has the lower  $X$  coordinate value is the start point. If the two joints have the same  $Z$  and  $X$  coordinate value, then the one that has the lower  $Y$  coordinate value is the start point.
- The local  $x$  axis is parallel to the global  $XZ$  plane, positive along the nominal wave propagation direction. If the cylinder's axis is along the global  $X$  direction, then the local  $x$  axis is parallel to the  $XZ$  plane, and positive along the negative global  $Z$  direction.
- The local  $y$  axis can be found assuming a right-handed Cartesian coordinate system.

### 7.1.3 Local to Global transformation

For regular members, the cylinder expression in global coordinate system can be found as follows:

$$\begin{Bmatrix} X \\ Y \\ Z \end{Bmatrix} = [C] \begin{Bmatrix} r \cos \theta \\ r \sin \theta \\ z \end{Bmatrix} + \begin{Bmatrix} \frac{X_s + X_e}{2} \\ \frac{Y_s + Y_e}{2} \\ \frac{Z_s + Z_e}{2} \end{Bmatrix}$$

where  $(X_s, Y_s, Z_s)$  and  $(X_e, Y_e, Z_e)$  are the start and end joints of the member in global coordinate system of the member, and  $[C]$  is the direction cosine matrix of the member axis and can be obtained as follows:

$$[C] = \begin{bmatrix} \frac{Z_e - Z_s}{L_{xz}} & -\frac{(X_e - X_s)(Y_e - Y_s)}{L_{xz}L} & \frac{X_e - X_s}{L} \\ 0 & \frac{L_{xz}}{L} & \frac{Y_e - Y_s}{L} \\ \frac{-X_e + X_s}{L_{xz}} & -\frac{(Z_e - Z_s)(Y_e - Y_s)}{L_{xz}L} & \frac{Z_e - Z_s}{L} \end{bmatrix}$$

where  $L_{xz} = \sqrt{(X_e - X_s)^2 + (Z_e - Z_s)^2}$  and  $L = \sqrt{(X_e - X_s)^2 + (Y_e - Y_s)^2 + (Z_e - Z_s)^2}$ . When  $X_e = X_s$  and  $Z_e = Z_s$ , the  $[C]$  matrix can be found as follows:

if  $Y_e < Y_s$   $Y_e > Y_s$  then

$$[C] = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{bmatrix}$$

else

$$[C] = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{bmatrix}$$

## 7.2 Wave Kinematics

The wave kinematics are modeled using Airy wave theory, which can be used to describe either regular or irregular waves. For regular waves, the wave elevation ( $\zeta$ ) is represented as a sinusoid with a single amplitude (wave height) and frequency. Airy wave theory also describes how the undisturbed fluid-particle velocities and accelerations decay exponentially with depth. Irregular or random waves can then be represented as a summation or superposition of multiple wave components, as described by an appropriate wave spectrum:

$$\zeta(t) = \frac{1}{2\pi} \int_{-\infty}^{\infty} W(\omega) \sqrt{2\pi S_{\zeta}^{2-sided}(\omega)} e^{j\omega t} d\omega$$

This equation represents the wave elevation as an inverse Fourier transform of the desired two-sided power spectral density,  $S_{\zeta}^{2-sided}$  where  $j$  is an imaginary number and  $\omega$  is an individual wave frequency.  $W(\omega)$  is the Fourier transform of a realization of a white Gaussian noise (WGN) time-series process with zero mean and unit variance (i.e., the so-called “standard normal distribution”). This realization is used to ensure that the individual wave components have a random phase and that the instantaneous wave elevation is normally- (i.e., Gaussian-) distributed with zero mean and with a variance, on average, equal to  $\sigma_{\zeta}^2 = \int_{-\infty}^{\infty} S_{\zeta}^{2-Sided}(\omega) d\omega$ .

Further details about the wave kinematics and how they are computed can be found in [Jonkman, 2007].

## 7.3 Current Model

The current model within HydroDyn is a superposition of three different types of sub-models. These sub-models follow the forms defined in the IEC 61400-3 offshore wind standard [IEC].

The first is a sub-surface current model for currents that are generated by tides, storm surge, atmospheric pressure variations, etc. This model is characterized by a simple 1/7 power law over the water depth,  $d$ .

$$U_{ss}(Z) = U_{0ss} \left( \frac{Z+d}{d} \right)^{\frac{1}{7}}$$

The second is near-surface currents generated by wind. This model is characterized by a linear distribution of the velocity with water depth, ending at zero at a prescribed depth,  $h_{ref}$  (in [IEC]  $h_{ref}$  is set at 20 m).

$$U_{NS}(Z) = U_{0NS} \left( \frac{Z + h_{ref}}{h_{ref}} \right), Z \in [-h_{ref}, 0] \quad \text{otherwise, } U_{NS}(Z) = 0$$

The third model is a depth-independent model, which sets the current velocity to a constant value across the water depth.

You can specify a unique heading direction for each of the three current models.

## 7.4 Potential Flow Theory

Three main approaches exist for modeling the hydrodynamic loads within HydroDyn, potential-flow theory, strip theory (via Morison's equation), or a combination. This section reviews the forces modeled in HydroDyn when using a linear potential flow theory approach.

### 7.4.1 Modeling Approach

In linear potential-flow theory, the forces and added mass are applied at the platform reference point. The components are:

$$\vec{F}_{WRP} = \vec{F}_W + \vec{F}_{HS} + \vec{F}_{RD_n} + \vec{F}_{AM}$$

where

$$\begin{aligned} \vec{F}_{AM} &= -AM_{RP} \vec{a}_P \\ \vec{F}_W &= \frac{1}{N} \sum_{k=-\frac{N}{2}-1}^{\frac{N}{2}} W[k] \sqrt{\frac{2\pi}{\Delta t}} S_{\zeta}^{2-Sided}(\omega) X(\omega, \beta) \Big|_{\omega=k\Delta\omega} e^{j\frac{2\pi kn}{N}} \\ \vec{F}_{HS} &= \rho g V_0 \{\delta\}_3 - C^{Hydrostatic} \end{aligned}$$

The general form of the convolution integral is:

$$\vec{F}_{RD} = \int_0^t K(t-\tau) \cdot \dot{x}(\tau) d\tau$$

But we discretize this and only consider a specific amount time history,  $N_{RD}$ :

$$\vec{F}_{RD_n} = \Delta t_{RD} \sum_{i=n-N_{RD}}^{n-1} K_{n-i-1} \dot{x}_i$$

The state for time step n is simply the structural velocities for the previous  $N_{RD}$  time steps. Or,

$$x_n^d = \begin{Bmatrix} \dot{x}_{n-1} \\ \dot{x}_{n-2} \\ \vdots \\ \dot{x}_{n-N_{RD}} \end{Bmatrix}$$

Therefore, at time step  $n$ , we can compute the  $n+1$  state, such that,

$$x_{n+1}^d = \begin{Bmatrix} \dot{x}_n \\ \dot{x}_{n-1} \\ \vdots \\ \dot{x}_{n-N_{RD}+1} \end{Bmatrix}$$

The radiation step size,  $\Delta t_{RD}$ , and the radiation kernel,  $K$ , are simply module parameters.

## 7.5 Morison's Equation

Morison's equation is applicable for calculating the hydrodynamic loads on cylindrical structures when (1) the effects of diffraction are negligible, (2), radiation damping is negligible, and (3) flow separation may occur. The relative form of Morison's equation accounts for wave loading from incident-wave-induced excitation, radiation-induced added mass, and flow-separation-induced viscous drag. In this section we review the representation of Morison's equation both when considering distributed forces along the length of the members (at nodes) and point loads at the ends (at the joints).

### 7.5.1 Modeling Approach

In the present version of HydroDyn, Morison forces are applied only along the portion of the member below the SWL. Wave stretching theory has not yet been implemented. In addition, the forces are applied at the original position of the structure, and not at the instantaneous position.

#### 7.5.1.1 Distributed Loads

For a Morison-only model, the distributed hydrodynamic loads applied along the length of a member are computed as:

$$\vec{F} = \vec{F}_I + \vec{F}_D + \vec{F}_B + \vec{F}_{MG} + \vec{F}_{F\_B} + \vec{F}_{AM\_M} + \vec{F}_{AM\_MG} + \vec{F}_{AM\_F}$$

where  $F_I$  is the inertia force,  $F_D$  the drag force,  $F_B$  the buoyancy force,  $F_{MG}$  the weight of the marine growth,  $F_{F\_B}$  the force due to fluid ballasting,  $F_{AM\_M}$  the added mass of the structure,  $F_{AM\_MG}$  the added mass due to marine growth, and  $F_{AM\_F}$  the added mass due to fluid ballasting. Details about each of these forces will be provided in the following sections. All of these forces except the buoyancy forces,  $\vec{F}_B$ , and  $\vec{F}_{F\_B}$ , are applied directly to a mesh node.

If a hybrid model is desired, which combines contributions from both potential-flow theory and Morison's equation, the only components that are considered for Morison's equation are:

$$\vec{F} = \vec{F}_D + \vec{F}_{F\_B} + \vec{F}_{AM\_F}$$

#### 7.5.1.1.1 Inertial Loads

The inertial force component of Morison's equation is associated with the fluid acceleration, and includes two terms. The first is the Froude-Krylov term associated with the unsteady pressure field generated by the undisturbed waves. This term can be controlled using the  $C_P$  coefficient, with a value of 1.0 being the default. The second term is the scattering force associated with the disruption of the fluid by the presence of the structure. This term is controlled by the coefficient of added mass,  $C_A$ . The equation below gives the full representation of the inertia force, which includes transverse and axial forces (represented by the  $Ax$  subscript).

$$\vec{F}_I = \begin{cases} (C_P + C_A) \rho_W \pi (R + t_{MG})^2 \left( \vec{a}_f - (\vec{a}_f \bullet \hat{k}) \hat{k} \right) + \left\{ C_{P_{Ax}} 2\pi (R + t_{MG}) \frac{\partial R}{\partial z} p_{dyn} + C_{A_{Ax}} \rho_W 2\pi (R + t_{MG})^2 \left| \frac{\partial R}{\partial z} \right| (\vec{a}_f \bullet \hat{k}) \right\} \hat{k} \\ 0 \\ 0 \\ 0 \end{cases}$$

where  $\frac{\partial R}{\partial z} = \frac{(R^e + t_{mg}^e) - (R^s + t_{mg}^s)}{(Z^e - Z^s)}$

It is noted that  $C_P + C_A = C_M$ , the inertia coefficient.  $C_P$  is called the dynamic pressure coefficient. By creating the dynamic pressure coefficient,  $C_M$  and  $C_A$  can be controlled independently.

#### 7.5.1.1.2 Viscous Drag

The second major component of Morison's equation is the viscous drag force, which is represented in the equation below. The viscous drag force is proportional to the square of relative velocity between the fluid and the structure, and is scaled using the coefficient of drag,  $C_D$ .

$$\vec{F}_D = \begin{cases} C_D \rho_W (R + t_{MG}) \left\| \vec{v}_{rel} - (\vec{v}_{rel} \bullet \hat{k}) \hat{k} \right\|_2 \left( \vec{v}_{rel} - (\vec{v}_{rel} \bullet \hat{k}) \hat{k} \right) \\ 0 \\ 0 \\ 0 \end{cases}$$

#### 7.5.1.1.3 Buoyancy

The next term presented is the buoyancy term, which is the force directed along the global Z-axis equal to the weight of the displaced fluid when the platform is in its undisplaced position.

$$\vec{F}_B = \rho_w g \left\{ \begin{array}{c} C \left\{ \begin{array}{c} C_{31} \pi (R + t_{MG})^2 \\ C_{32} \pi (R + t_{MG})^2 \\ -2\pi (R + t_{MG}) \frac{\partial R}{\partial z} Z \end{array} \right\} \\ C \left\{ \begin{array}{c} -C_{32} \pi \frac{\partial R}{\partial z} (R + t_{MG})^3 \\ +C_{31} \pi \frac{\partial R}{\partial z} (R + t_{MG})^3 \\ 0 \end{array} \right\} \end{array} \right\}$$

#### 7.5.1.1.4 Marine Growth Weight

Marine growth is considered in the force equation by adding its weight, as shown below, where  $t_{MG}$  is the thickness of the marine growth and  $\rho_{MG}$  its density.

$$\vec{F}_{MG} = \left\{ \begin{array}{c} 0 \\ 0 \\ -\rho_{mg} g \pi \left( (R + t_{MG})^2 - R^2 \right) \\ 0 \\ 0 \\ 0 \end{array} \right\}$$

#### 7.5.1.1.5 Ballasting

One can choose to add water ballasting to the individual members. The effect of this ballasting is considered in the equation below, where  $Z_{fs}$  is the free-surface height of the ballast fluid in a member.

$$\vec{F}_{F\_B} = -\rho_f \mathbf{g} \left\{ \begin{array}{c} C \left\{ \begin{array}{c} C_{31} \pi (R-t)^2 \\ C_{32} \pi (R-t)^2 \\ -2\pi (R-t) \frac{\partial R}{\partial z} (Z - Z_{fs}) \end{array} \right\} \\ C \left\{ \begin{array}{c} -C_{32} \pi \frac{\partial R}{\partial z} (R-t)^3 \\ C_{31} \pi \frac{\partial R}{\partial z} (R-t)^3 \\ 0 \end{array} \right\} \end{array} \right\}$$

#### 7.5.1.1.6 Hydrodynamic Added Mass

The next group of terms is associated with the added mass of the structure, which is proportional to the acceleration of the structure. The added mass is the inertia added to a system because an accelerating body must move some volume of surrounding fluid as it moves through it. In the equations below, both transverse and axial terms are shown.

$$AM_M = \rho_w \pi (R + t_{MG})^2 \left[ \begin{array}{cc} \left[ C_A \left( I - \hat{k} \hat{k}^T \right) - 2C_{Ax} \left| \frac{\partial R}{\partial z} \right| \hat{k} \hat{k}^T \right] & [0] \\ [0] & [0] \end{array} \right]$$

$$\vec{F}_{AM\_M} = -AM_M \left\{ \begin{array}{c} \vec{a}_s \\ \vec{\alpha}_s \end{array} \right\}$$

#### 7.5.1.1.7 Added Mass due to Marine Growth

If marine growth is applied to the structure, this additional volume will alter the added mass calculation. Here, the influence of the marine growth is captured through an additional term.

$$AM_{MG} = \rho_{mg} \pi \left( (R + t_{MG})^2 - R^2 \right) \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

$$\vec{F}_{AM\_MG} = -AM_{MG} \left\{ \begin{array}{c} \vec{a}_s \\ \vec{\alpha}_s \end{array} \right\}$$

#### 7.5.1.1.8 Added Mass due to Ballasting

Similarly, the added mass is altered by the existence of fluid ballasting, which is captured in the following equations.

$$AM_F = \rho_f \pi (R - t_M)^2 \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

$$\vec{F}_{AM\_F} = -AM_F \begin{Bmatrix} \vec{a}_s \\ \vec{\alpha}_s \end{Bmatrix}$$

#### 7.5.1.2 Lumped Loads at member ends

The previous section covered distributed forces along the length of a member. Now, lumped forces at member ends are considered.

When using a Morison-only model, the lumped forces for Morison's equation at the member ends include the following components:

$$\vec{F} = \vec{F}_I + \vec{F}_D + \vec{F}_B + \vec{F}_{F\_B} + \vec{F}_{AM}$$

However, if the member is modeled using a hybrid approach combining both potential flow theory and Morison's equation, only the following terms are considered:

$$\vec{F} = \vec{F}_D + \vec{F}_{F\_B}$$

The influences of the individual terms in Morison's equation in a lumped formulation are the same as the description for the distributed forces, but the implementation changes. Whereas the distributed forces considered the projected area and diameter of the member assuming a cylindrical geometry, at the ends the member is considered a flat plate in Morison's equation.

### 7.5.1.2.1 Inertial Loads

$$\vec{F}_I^s = \left\{ \begin{array}{c} C^s \left\{ \begin{array}{c} 0 \\ 0 \\ C_{P_{Ax}} \pi (R^s + t_{MG}^s)^2 p_{dyn} \end{array} \right\} + \frac{C_{A_{Ax}} \rho_W \vec{V}_n (\vec{a}_f \bullet \vec{V}_n)}{\sqrt{(\vec{V}_n \bullet \vec{V}_n)}} \\ 0 \\ 0 \\ 0 \end{array} \right\} \quad (32)$$

$$\vec{F}_I^e = \left\{ \begin{array}{c} -C^e \left\{ \begin{array}{c} 0 \\ 0 \\ C_{P_{Ax}} \pi (R^e + t_{MG}^e)^2 p_{dyn} \end{array} \right\} + \frac{C_{A_{Ax}} \rho_W \vec{V}_n (\vec{a}_f \bullet \vec{V}_n)}{\sqrt{(\vec{V}_n \bullet \vec{V}_n)}} \\ 0 \\ 0 \\ 0 \end{array} \right\} \quad (33)$$

where  $\vec{V}_n = \sum_i^M \frac{2}{3} \pi (R^i + t_{MGi})^3 \hat{n}_i$

The terms in  $\vec{F}_I^s$  and  $\vec{F}_I^e$  involving  $C_{A_{Ax}}$  must be divided by M and distributed equally to the start/end node each member at each joint.

### 7.5.1.2.2 Viscous Drag

$$\vec{A}_n = \sum_i^M A_i \hat{n}_i$$

$$\vec{F}_D = \left\{ \begin{array}{c} \frac{C_{D_{Ax}} \rho_W \vec{A}_n \|\vec{v}_{rel} \bullet \vec{A}_n\|_2 (\vec{v}_{rel} \bullet \vec{A}_n)}{4 (\vec{A}_n \bullet \vec{A}_n)} \\ 0 \\ 0 \\ 0 \end{array} \right\} \quad (31)$$

Equation 31 is the total lumped drag at a joint, since the simulation mesh consists of M co-located lumped nodes,  $\vec{F}_D$  is actually  $\frac{\vec{F}_D}{M}$ , for each simulation node.

### 7.5.1.2.3 Buoyancy

$$\vec{F}_B^s = \rho_w \mathbf{g} \left\{ \begin{array}{c} C_s \left\{ \begin{array}{c} 0 \\ 0 \\ -Z^s \pi (R^s + t_{MG}^s)^2 \end{array} \right\} \\ -\frac{\pi}{4} C_{32} (R^s + t_{MG}^s)^4 \\ C_s \left\{ \begin{array}{c} \frac{\pi}{4} C_{31} (R^s + t_{MG}^s)^4 \\ 0 \end{array} \right\} \end{array} \right\} \quad (35)$$

$$\vec{F}_B^e = \rho_w \mathbf{g} \left\{ \begin{array}{c} C_e \left\{ \begin{array}{c} 0 \\ 0 \\ Z^e \pi (R^e + t_{MG}^e)^2 \end{array} \right\} \\ \frac{\pi}{4} C_{32} (R^e + t_{MG}^e)^4 \\ C_e \left\{ \begin{array}{c} -\frac{\pi}{4} C_{31} (R^e + t_{MG}^e)^4 \\ 0 \end{array} \right\} \end{array} \right\} \quad (36)$$

### 7.5.1.2.4 Ballasting

$$\vec{F}_{F\_B}^s = -\rho_f \mathbf{g} \left\{ \begin{array}{c} C^s \left\{ \begin{array}{c} 0 \\ 0 \\ -(Z^s - Z^{fs}) \pi (R^s - t_M^s)^2 \end{array} \right\} \\ -\frac{\pi}{4} C_{32} (R^s - t_M^s)^4 \\ C^s \left\{ \begin{array}{c} \frac{\pi}{4} C_{31} (R^s - t_M^s)^4 \\ 0 \end{array} \right\} \end{array} \right\}, \quad (37)$$

$$\vec{F}_{F\_B}^e = -\rho_f g \left\{ \begin{array}{c} C^e \left\{ \begin{array}{c} 0 \\ 0 \\ (Z^e - Z^{fs}) \pi (R^e - t_M^e)^2 \end{array} \right\} \\ \left\{ \begin{array}{c} \frac{\pi}{4} C_{32} (R^e - t_M^e)^4 \\ -\frac{\pi}{4} C_{31} (R^e - t_M^e)^4 \\ 0 \end{array} \right\} \end{array} \right\}$$

#### 7.5.1.2.5 Hydrodynamic Added Mass

$$\vec{F}_{AM} = \left\{ \begin{array}{c} \frac{-C_{A_{Ax}} \rho_W \vec{V}_n (\vec{a}_s \bullet \vec{V}_n)}{\sqrt{(\vec{V}_n \bullet \vec{V}_n)}} \\ 0 \\ 0 \\ 0 \end{array} \right\}$$

This is the total lumped added mass force at a joint, since the simulation mesh consists of M co-located lumped nodes,  $\vec{F}_{AM}$  is actually  $\frac{\vec{F}_{AM}}{M}$ , for each simulation node.

Note that  $\hat{n}_i$  is the outward facing normal vector, so,  $\hat{n}_i = -\hat{k}_i$  at the start (s) of a member and  $\hat{n}_i = \hat{k}_i$  at the end (e) of a member.

#### 7.5.2 Simulation Discretization

HydroDyn refines the input geometry of joints and members into a resulting set of nodes and elements using the following algorithm:

1. Copy initial input geometry of joints/members to an initial node/element description.
2. For each element, swap the element nodes if they do not satisfy the specifications of Section 7.1.2.
3. For each element, determine if the element needs to be split for any of the following reasons; adding a node and an element to the mesh for each positive test:
  - The element is filled and the free-surface elevation lies within the element; add node at free-surface elevation.

- The element crosses the ***MSL2SWL*** elevation; add node at ***MSL2SWL*** elevation.
  - The element crosses the seabed; add node at seabed elevation.
  - The element crosses the upper and/or lower marine-growth elevations; add one or two nodes corresponding to the upper and/or lower marine growth elevations.
4. For each resulting element, if its length is greater than ***MDivSize*** for its associated input member, then subdivide into the necessary number of additional elements such that each element's length is less than or equal to ***MDivSize***. Any new nodes created as a part of this subdivision are referred to as "interior nodes".
  5. Finally, for each non-interior node, determine if it connects to more than one element. If so, make N-1 copies of that node, where N is the number of elements connecting to the node. Redefine the connectivity of these connected elements such that the original node and the new nodes connect to only one element.

## 8 Future Work

This list contains features that we will implement in future releases:

- Enable times-series input motions for Morison members in the standalone HydroDyn (*MorisonInputsMod* = 2)
- Enable tight-coupling to FAST, including linearization.
- Enable wave stretching (*WaveStMod* > 0).
- Enable full support for floating platform force flags.
- Enable joint overlap calculations (*JointOvrtp* = 1).
- Support for user-defined wave time history.
- Enable auto-generation of all possible output channels (*OutAll* = TRUE).
- Allow for a WAMIT reference point location other than (0,0,0).
- Allow *RdtnDT* to be independent from the FAST simulation time step
- Complete implementation of second-order wave kinematics and second-order potential-flow hydrodynamic loads.
- Add distributed axial viscous-drag loads on tapered members.
- Add rotational inertia terms for fluid-filled members and marine growth.
- Calculate the effective 6x6 added-mass matrix from strip-theory members and place in the HydroDyn summary file.
- Add graphics/animation capability to visualize the substructure geometry and motion, wave elevation, and hydrodynamic loads.
- Further validation with test data.
- Add nonlinear regular wave kinematics models for fixed-bottom substructures.
- Add breaking wave-impact loads for fixed-bottom substructures.
- Add floating platform hydro-elastics.
- Add pressure mapping for floating platforms.
- Fix the problem whereby HydroDyn can't be run after compiling with gFortran.
- Added automated computation and use of hydrostatic restoring matrix for strip-theory members.

```

## Appendix C. List of Output Channels

This is a list of all possible output parameters for the HydroDyn module. The names are grouped by meaning, but can be ordered in the OUTPUT CHANNELS section of the HydroDyn input file as you see fit.  $MaN\beta$ , refers to node  $\beta$  of member  $\alpha$ , where  $\alpha$  is a number in the range [1,9] and corresponds to row  $\alpha$  in the MEMBER OUTPUT LIST table and  $\beta$  is a number in the range [1,9] and corresponds to location  $\beta$  in the **NodeLocs** list of that table entry.  $Ja$  refers to joint  $\alpha$ , where  $\alpha$  is a number in the range [1,9] and corresponds to row  $\alpha$  in the JOINT OUTPUT LIST table. All outputs are in the global inertial-frame coordinate system.

Channel Name(s)	Units	Description
<i>Wave and Current Kinematics</i>		
Wave1Elev, Wave2Elev, ..., Wave9Elev	(m)	Wave elevations (up to 9 designated locations)
$MaN\beta V_{xi}$ , $MaN\beta V_{yi}$ , $MaN\beta V_{zi}$	(m/s), (m/s), (m/s)	Fluid particle velocities at $MaN\beta$
$MaN\beta A_{xi}$ , $MaN\beta A_{yi}$ , $MaN\beta A_{zi}$	(m/s <sup>2</sup> ), (m/s <sup>2</sup> ), (m/s <sup>2</sup> )	Fluid particle accelerations at $MaN\beta$
$MaN\beta DynP$	(Pa)	Fluid particle dynamic pressure at $MaN\beta$
$JaV_{xi}$ , $JaV_{yi}$ , $JaV_{zi}$	(m/s), (m/s), (m/s)	Fluid particle velocities at $Ja$
$JaA_{xi}$ , $JaA_{yi}$ , $JaA_{zi}$	(m/s <sup>2</sup> ), (m/s <sup>2</sup> ), (m/s <sup>2</sup> )	Fluid particle accelerations at $Ja$
$JaDynP$	(Pa)	Fluid particle dynamic pressure at $Ja$
<i>Total and Additional Loads</i>		
AddFxi, AddFyi, AddFzi, AddMxi, AddMyi, AddMzi	(N), (N), (N), (N·m), (N·m), (N·m)	Forces and moments due to additional preload, stiffness, and damping at the WRP
HydroFxi, HydroFyi, HydroFzi, HydroMxi, HydroMyi, HydroMzi	(N), (N), (N), (N·m), (N·m), (N·m)	Total integrated hydrodynamic loads from both potential flow and strip theory at the WRP
<i>Loads from Potential-Flow Solution</i>		
WavesFxi, WavesFyi, WavesFzi, WavesMxi, WavesMyi, WavesMzi	(N), (N), (N), (N·m), (N·m), (N·m)	Wave-excitation loads from linear diffraction at the WRP
HdrStcFxi, HdrStcFyi, HdrStcFzi, HdrStcMxi, HdrStcMyi, HdrStcMzi	(N), (N), (N), (N·m), (N·m), (N·m)	Hydrostatic loads at the WRP
RdtnFxi, RdtnFyi, RdtnFzi, RdtnMxi, RdtnMyi, RdtnMzi	(N), (N), (N), (N·m), (N·m), (N·m)	Radiation loads at the WRP
<i>Structural Motions</i>		
WRPSurge, WRPSway, WRPHeave, WRPRoll, WRPPitch, WRPYaw	(m), (m), (m), (rad), (rad), (rad)	Displacements and rotations at the WRP
WRPTVxi, WRPTVyi, WRPTVzi, WRPRVxi, WRPRVyi, WRPVzi	(m/s), (m/s), (m/s), (rad/s), (rad/s), (rad/s)	Translational and rotational velocities at the WRP
WRPTAxi, WRPTAyi, WRPTAzi, WRPRAxi, WRPRAyi, WRPAzi	(m/s <sup>2</sup> ), (m/s <sup>2</sup> ), (m/s <sup>2</sup> ), (rad/s <sup>2</sup> ), (rad/s <sup>2</sup> ), (rad/s <sup>2</sup> )	Translational and rotational accelerations at the WRP
$MaN\beta STV_{xi}$ , $MaN\beta STV_{yi}$ , $MaN\beta STV_{zi}$	(m/s), (m/s), (m/s)	Structural translational velocities at $MaN\beta$
$MaN\beta STA_{xi}$ , $MaN\beta STA_{yi}$ , $MaN\beta STA_{zi}$	(m/s <sup>2</sup> ), (m/s <sup>2</sup> ), (m/s <sup>2</sup> )	Structural translational accelerations at $MaN\beta$

JaSTVxi, JaSTVyi, JaSTVzi	(m/s), (m/s), (m/s)	Structural translational velocities at Ja
JaSTAx <sub>i</sub> , JaSTAy <sub>i</sub> , JaSTAz <sub>i</sub>	(m/s <sup>2</sup> ), (m/s <sup>2</sup> ), (m/s <sup>2</sup> )	Structural translational accelerations at Ja
<i>Distributed Loads (Per Unit Length) on Members</i>		
MaNβFDxi, MaNβFDyi, MaNβFDzi	(N/m), (N/m), (N/m)	Viscous-drag force at MaNβ
MaNβFixi, MaNβFiyi, MaNβFizi	(N/m), (N/m), (N/m)	Fluid-inertia force at MaNβ
MaNβFBxi, MaNβFByi, MaNβFBzi, MaNβMBxi, MaNβMByi, MaNβMBzi	(N/m), (N/m), (N/m), (N·m/m), (N·m/m), (N·m/m)	Buoyancy loads at MaNβ
MaNβFBFxi, MaNβFBFyi, MaNβFBFzi, MaNβMBFxi, MaNβMBFyi, MaNβMBFzi	(N/m), (N/m), (N/m), (N·m/m), (N·m/m), (N·m/m)	Negative buoyancy loads due to flooding/ballasting at MaNβ
MaNβFMGxi, MaNβFMGyi, MaNβFMGzi	(N/m), (N/m), (N/m)	Forces due to marine growth weight at MaNβ
MaNβFAMxi, MaNβFAMyi, MaNβFAMzi	(N/m), (N/m), (N/m)	Hydrodynamic added-mass forces at MaNβ
MaNβFAGxi, MaNβFAGyi, MaNβFAGzi	(N/m), (N/m), (N/m)	Marine growth mass inertia forces at MaNβ
MaNβFAFxi, MaNβFAFyi, MaNβFAFzi	(N/m), (N/m), (N/m)	Flooding/ballasting mass inertia forces at MaNβ
MaNβFAxi, MaNβFAyi, MaNβFAzi	(N/m), (N/m), (N/m)	Total effective added-mass forces at MaNβ
<i>Lumped Loads at Joints</i>		
JaFDxi, JaFDyi, JaFDzi	(N), (N), (N)	Viscous-drag force at Ja
JaFixi, JaFiyi, JaFizi	(N), (N), (N)	Fluid-inertia force at Ja
JaFBxi, JaFByi, JaFBzi, JaMBxi, JaMByi, JaMBzi	(N), (N), (N), (N·m), (N·m), (N·m)	Buoyancy loads at Ja
JaFBFxi, JaFBFyi, JaFBFzi, JaMBFxi, JaMBFyi, JaMBFzi	(N), (N), (N), (N·m), (N·m), (N·m)	Negative buoyancy loads due to flooding/ballasting at Ja
JaFAMxi, JaFAMyi, JaFAMzi	(N), (N), (N)	Hydrodynamic added-mass forces at Ja

## Appendix D. Compiling Stand-alone HydroDyn

See the FAST documentation for instructions on how to compile HydroDyn coupled to FAST.

*Future versions of the manual will include compiling instructions for building the stand-alone HydroDyn program.*

## Appendix E. Major Changes in HydroDyn

HydroDyn when first released was included as an undocumented feature of FAST and packaged with the FAST archive. Since v2.00, the former software called “HydroDyn” has been separated into a distinct module packaged separately from FAST (but still coupled to FAST) and itself has been split into two pieces of software, each following the FAST modularization framework. This appendix outlines significant modifications to HydroDyn made with each public release, starting with v2.00.

### v2.01 (June 2014)

Version 2.01 integrates with the [FAST v8 software](#) v8.08.00c-bjj.

- **Driver input file changes**
  - Enabled *MorisonInputsMod* option for steady-state Morison inputs
  - Added wave-elevation output section
- **Primary input file changes**
  - ENVIRONMENTAL CONDITIONS section
    - Enabled the *MSL2SWL* parameter
  - WAVES section
    - Added parameters supporting multi-directional waves: *WaveDirMod*, *WaveDirSpread*, *WaveNDir*, *WaveDirRange*
  - Added 2<sup>ND</sup>-ORDER WAVES section
  - FLOATING PLATFORM section
    - Added support for *RdtnDT* to be set to “DEFAULT” to match driver code time step
  - Added 2<sup>ND</sup>-ORDER FLOATING PLATFORM FORCES section
  - HEAVE COEFFICIENTS section renamed AXIAL COEFFICIENTS
    - Renamed *HvCoefID* to *AxCoeffID*
    - Renamed *CdHv* to *AxCd*
    - Renamed *CaHv* to *AxCa*
    - Added axial dynamic-pressure coefficient, *AxCp*
  - SIMPLE HYDRODYNAMIC COEFFICIENTS section
    - Added dynamic-pressure coefficients: *SimplCp*, *SimplCpMG*
    - Added parameters for axial coefficients: *SimplAxCa*, *SimplAxCaMG*, *SimplAxCp*, *SimplAxCpMG*
  - DEPTH-BASED HYDRODYNAMIC COEFFICIENTS section
    - Added dynamic-pressure coefficients: *DpthCp*, *DpthCpMG*

- Added parameters for axial coefficients: *DpthAxCa*, *DpthAxCaMG*, *DpthAxCp*, *DpthAxCpMG*
  - MEMBER-BASED HYDRODYNAMIC COEFFICIENTS section
    - Added dynamic-pressure coefficients: *MemberCp1*, *MemberCp2*, *MemberCpMG1*, *MemberCpMG2*,
    - Added parameters for axial coefficients: *MemberAxCa1*, *MemberAxCa2*, *MemberAxCaMG1*, *MemberAxCaMG2*, *MemberAxCp1*, *MemberAxCp2*, *MemberAxCpMG1*, *MemberAxCpMG2*
  - Consolidated the two sections for output channel labels into a single OUTPUT CHANNELS section.
    - Numerous changes and additions to the available channel labels, see Appendix C
- **Output file changes**
  - Modified file naming convention to match FAST convention
  - Summary file saw several changes
    - Now includes WAMIT-body volume and buoyancy table
    - Existing volume, buoyancy, and weight tables were moved to the start of the file
    - The radiation kernel and wave kinematics tables were moved to the end of the file
    - The node and element tables were altered
    - New wave-elevation outputs file available when using stand-alone HydroDyn
    - All units are now SI (m, N, s)
  - Results file
    - All units are now SI (m, N, s)
- **New or Modified Hydrodynamics**
  - Added multi-directional waves
  - Combined Froude-Kriloff (dynamic-pressure) loads into the inertial loads
  - Added option whereby if simulation time is greater than *WaveTMax*, waves repeat
  - Added lumped inertial loads
  - Altered lumped added-mass equation
  - Altered distributed inertial-load equation
  - Altered fluid-domain checks for when to compute hydrodynamic loads

- Included the platform added-mass loads in the radiation load outputs (*RdtnFxi*, *RdtnFyi*, etc.)
- **Miscellaneous**
  - Restructured the calculation of loads due to additional stiffness, damping so they work when *HasWAMIT* = FALSE
  - Wave elevations can now be output when *HasWAMIT* = FALSE
  - Changed terminology from platform reference point to WAMIT reference point (WRP)
  - Added improved error handling when parsing input file
- **Significant bug Fixes**
  - Fixed bug for regular waves with phase
  - Fixed bug in computation of wave kinematics for current cases
  - Fixed bug that could prevent filled buoyancy from being computed
  - Fixed bug where a model using WAMIT could still report marine-growth volume in the summary file
  - Fixed bug with transverse drag calculation: wasn't including all components of relative velocity
  - Fixed bug with computation of lumped added-mass matrix
  - Fixed bug in the mesh-mapping of HydroDyn to ElastoDyn
  - Fixed bug where dynamic-pressure load terms, and buoyancy, and drag might not be calculated even when *PropWAMIT* = FALSE
  - Fixed bug with reported units of output channels
  - Fixed bug so that WAMIT-related calculations now account for *PtfmCOBxt* and *PtfmCOByt*
  - Fixed bug when user set *WaveNDamp* = TRUE when *WaveMod* = 1

### v2.00.01 (October 2013)

The major changes in version 2.00 are:

- Version 2.00 integrates with the [FAST v8 software](#) v8.03-bjj.
- Mooring lines have been removed from HydroDyn. The mooring line modeling is now being handled in a different FAST module. You can however use the additional stiffness and damping matrices to model a mooring line system within HydroDyn.
- Multi-member structures can now be modeled within HydroDyn (applicable e.g. to fixed-bottom tripod and jacket structures, as well as thin members (e.g., braces/spokes) of floating platforms). This modeling implement's Morison's equation for multiple slender cylinders, inclined and tapered members, inertia/drag/added mass/buoyancy/dynamic pressure loads, filled/flooded effects, and marine growth effects.

- Hybrid models with both linear radiation/diffraction calculations and Morison Equation calculations are possible.
- Added a linear state-space-based radiation formulation to be used together with [SS\\_Fitting](#).
- The new implementation has well-defined data exchange interfaces ([following the FAST modularization framework](#)) which should make integration of HydroDyn into other multi-physics software packages much simpler.
